SPECIALIZATIONS OF ONE-PARAMETER FAMILIES OF POLYNOMIALS

by Farshid HAJIR & Siman WONG (*)

Abstract. — Let $K$ be a number field, and suppose $\lambda(x, t) \in K[x, t]$ is irreducible over $K(t)$. Using algebraic geometry and group theory, we describe conditions under which the $K$-exceptional set of $\lambda$, i.e. the set of $\alpha \in K$ for which the specialized polynomial $\lambda(x, \alpha)$ is $K$-reducible, is finite. We give three applications of the methods we develop. First, we show that for any fixed $n \geq 10$, all but finitely many $K$-specializations of the degree $n$ generalized Laguerre polynomial $L_n(t)(x)$ are $K$-irreducible and have Galois group $S_n$. Second, we study specializations of the modular polynomial $\Phi_n(x, t)$ (which vanishes on the $j$-invariants of pairs of elliptic curves related by a cyclic $n$-isogeny), and show that for any $n \geq 53$, all but finitely many of the $K$-specializations of $\Phi_n(x, t)$ are $K$-irreducible and have Galois group containing $\text{SL}_2(\mathbb{Z}/n)/\{\pm I\}$. Third, for a simple branched cover $\pi: Y \to \mathbb{P}_K^1$ of degree $n \geq 7$ and of genus at least 2, all but finitely many $K$-specializations are $K$-irreducible and have Galois group $S_n$.

Résumé. — Soient $K$ un corps de nombres et $\lambda(x, t) \in K[x, t]$ un polynôme irréductible sur $K(t)$. À partir de la géométrie algébrique et de la théorie des groupes, nous donnons des conditions suffisantes pour que l’ensemble $K$-exceptionnel de $\lambda$, c’est-à-dire l’ensemble des éléments $\alpha$ de $K$ tels que $\lambda(x, \alpha)$ est réductible sur $K$, soit fini. Nos méthodes nous permettent alors de développer trois applications. Tout d’abord, nous obtenons que pour tout entier $n$ plus grand que 10, à l’exception d’un nombre fini de cas, la $K$-spécialisation du polynôme de Laguerre généralisé $L_n(t)(x)$ de degré $n$ est $K$-irréductible et a pour groupe de Galois $S_n$. Ensuite, nous étudions les spécialisations du polynôme modulaire $\Phi_n(x, t)$ (celui-ci s’annule en les $j$-invariants des paires de courbes elliptiques reliées entre elles par une $n$-isogénie cyclique). Nous montrons que pour tout $n \geq 53$, à l’exception d’un nombre fini de cas, les $K$-spécialisations de $\Phi_n(x, t)$ sont $K$-irréductibles et ont un groupe de Galois contenant $\text{SL}_2(\mathbb{Z}/n)/\{\pm I\}$. Enfin, nous obtenons que pour un revêtement simple $\pi: Y \to \mathbb{P}_K^1$ de degré $n \geq 7$ et de genre au moins 2, à l’exception d’un nombre fini de cas, les $K$-spécialisations de $\pi$ sont $K$-irréductibles et ont pour groupe de Galois $S_n$.

1. Introduction

Let $K$ be a number field. Consider a polynomial $\lambda(x, t) \in K[x, t]$ which is non-constant in each of $x$ and $t$; it can be viewed as a one-parameter family of $K$-polynomials in $x$. If $\lambda$ is irreducible in $K[x, t]$, the Hilbert irreducibility theorem furnishes infinitely many $\alpha \in K$ for which $\lambda(x, \alpha)$ is $K$-irreducible. It is then natural to study the set of $\alpha \in K$ with reducible specialization. These exceptional sets are thin sets [31, §9.6], and the example $x^n - t$ shows that they can be infinite. Using techniques from diophantine analysis, Fried [13] bounded the number of exceptional specializations of bounded height. Exceptional sets for concrete families have also been examined; for example the irreducibility and Galois group of the generalized Laguerre polynomial

$$L_n^{(t)}(x) = \sum_{j=0}^{n} (-x)^j \binom{n}{j} \prod_{k=j+1}^{n} (t + k).$$

for various rational values of the parameter $t$ were studied by Schur [28], [29]; more recently, Feit [10] used them to solve the inverse Galois problem over $\mathbb{Q}$ for certain double covers of the alternating group $A_n$. See also [15], [17], [30], [16], for other related results. Note that in the papers just cited, the focus is primarily on a related, but different, question from the one we began with, namely that of irreducibility and Galois properties of $L_n^{(\alpha_n)}(x)$ for suitable sequences $\{\alpha_n\}_n$. For example, the case $\alpha_n = -1 - n$ corresponds to the truncated exponential polynomial studied by Schur [28]. For the latter type of question, the $p$-adic Newton polygon is a powerful tool. For example, in Filaseta-Lam [11] it is shown that if we fix $\alpha \in \mathbb{Q} - \mathbb{Z}_{<0}$, then $L_n^{(\alpha)}(x)$ is $\mathbb{Q}$-irreducible for $n$ sufficiently large, while in Filaseta-Trifonov [12], Grosswald’s conjecture, to the effect that $L_n^{(-1-2n)}(x)$ (i.e. the $n$-th degree Bessel polynomial) is $\mathbb{Q}$-irreducible for every $n$, is proved. The Newton Polygon approach, however, does not appear to be well-suited to the problem under consideration here, namely that of studying exceptional specializations of $L_n^{(t)}(x)$ for $n$ fixed.

In this paper we investigate the exceptional set of a given $\lambda(x, t)$ from the algebro-geometric and group-theoretic points of view. First, note that $\lambda(x, t)$ defines a 1-dimensional subvariety $X_\lambda \subset \mathbb{P}^2_K$. To say that the specialization of $\lambda$ at $t = \alpha$ has a $K$-rational root is to say that the fiber above $\alpha$ of the projection-to-$t$ map has a $K$-rational point. Say $X_\lambda$ is in fact absolutely irreducible; then, by Faltings, at most finitely many $K$-specializations of $\lambda$ have a $K$-rational root if $X_\lambda$ has genus $\geq 2$. More generally, a result of Müller [25] leads to an irreducibility criterion for specializations in terms
of the genus of intermediate subfields of $K'/K(t)$ where $K'$ is the Galois closure of $\lambda(x,t)$ over the function field $K(t)$ (cf. also the related results of Dèbes and Fried [6]).

In Sections 2, 4, and 5, we refine this geometric criterion in two ways. First, we expand its scope to specializations which are not only irreducible but whose Galois group coincides with the geometric Galois group of the cover. Second, we reformulate it in terms of the ramification of the corresponding branched cover. Thanks to recursive properties of $L_n^{(t)}(x)$, the ramification data of the projection-to-$t$ map can be expressed in terms of information about the conjugacy classes of maximal subgroups of $S_n$. The analysis of this ramification data in terms of maximal subgroups is somewhat delicate and constitutes the technical core of the proof of the following result.

**Theorem 1.** — Let $K$ be a number field.

(a) Fix $n \geq 5$. Then for all but finitely many $\alpha \in K$, $L_n^{(\alpha)}(x)$ is $K$-irreducible and its Galois group (over $K$) contains $A_n$. For fixed $n \geq 10$, this Galois group is exactly $S_n$ except for finitely many $\alpha \in K$.

(b) Let $R$ be a finitely generated subring of $K$. If $n \geq 6$, then for all but finitely many $\alpha \in R$, the Galois group over $K$ of $L_n^{(\alpha)}(x)$ is exactly $S_n$.

**Remark 1.** — Note that Theorem 1 is optimal in two ways. First, for $6 \leq n \leq 9$, the set of $\alpha \in K$ for which the discriminant of $L_n^{(\alpha)}(x)$ is a square in $K$ turns out to be parameterized by a curve of geometric genus one, so for suitable $K$ there are infinitely many specializations with even Galois group. And when $n = 5$, the square discriminants are parameterized by a curve of geometric genus zero, so there are fields $K$ and finitely generated subrings $R$ of $K$ over which there are infinitely many even specializations. Second, $L_4^{(t)}(x) = 0$ is a model (cf. [16]) of the elliptic curve $384H2$ in Cremona’s table. This curve has Mordell-Weil rank 1 over $\mathbb{Q}$, so over any number field $K$ there are infinitely many $\alpha \in K$ for which $L_4^{(\alpha)}(x)$ has a $K$-rational linear factor. However, the exceptional set in Theorem 1 is captured by rational points on curves of high geometric genus, so it would be difficult to make the theorem effective.

As we mentioned earlier, the study of the irreducibility properties of classical families of orthogonal polynomials has a long history. In most previous work on this topic, however, one studies “families” parametrized by the degree alone, that is to say for each $n \geq 1$, one has a univariate polynomial $f_n$ of degree $n$ whose irreducibility is to be established and whose Galois group is to be computed. These types of questions have a different flavor, and the
difficulties tend to be more arithmetic as opposed to algebraic: we have mentioned already the recent success of Filaseta and Trifonov in treating Bessel polynomials; for the family of Legendre polynomials, on the other hand, only very partial results are currently known these and quite a few other specializations of the 3-variable family of Jacobi polynomials \( P_n^{(\alpha,\beta)} \) seem to present difficulties of a higher order of magnitude. One benefit of investigating our question of exceptional specializations of Laguerre polynomials of fixed degree is to establish the effectiveness of our techniques for the higher-dimensional case of Jacobi polynomials, which we hope to treat in a future work.

Before we develop the tools necessary for proving Theorem 1, we illustrate the use of Müller’s criterion by applying it to another well-studied polynomial, namely the modular polynomial \( \Phi_n(x,j) \). This monic \( \mathbb{Z} \)-polynomial plays a central role in the theory of elliptic curves; it is determined up to a scalar multiple by the property that two elliptic curves over \( \mathbb{C} \) with \( j \)-invariants \( j_1, j_2 \) are related by a cyclic \( n \)-isogeny if and only if \( \Phi_n(j_1, j_2) = 0 \). It is irreducible over \( \mathbb{C}(j) \), and its Galois group over \( \mathbb{Q}(j) \) is \( \text{PGL}_2(\mathbb{Z}/n) \).

For any integer \( n > 1 \) and any prime \( p \), define

\[
Q_{p,n} = \begin{cases} 
\text{unique quadratic ext. of } \mathbb{Q} \text{ of conductor } p & \text{if } p > 2 \text{ and } p \mid n, \\
\text{unique biquadratic ext. of } \mathbb{Q} \text{ of conductor } 8 & \text{if } p = 2 \text{ and } 8 \mid n, \\
\text{unique quadratic ext. of } \mathbb{Q} \text{ of conductor } 4 & \text{if } p = 2 \text{ and } 4 \mid |n, \\
\mathbb{Q} & \text{otherwise.}
\end{cases}
\]

For any number field \( K \) and any \( n > 1 \), denote by \( \tilde{K}_n \) the compositum of \( K \) with all \( Q_{p,n} \) as \( p \) runs over the prime divisors of \( n \); note that this is a finite extension of \( K \).

**Theorem 2.** — Let \( n \geq 53 \), and let \( K \) be a number field. Then for all but finitely many \( \alpha \in \tilde{K}_n \), \( \Phi_n(x,\alpha) \) is \( \tilde{K}_n \)-irreducible, and its Galois group over \( \tilde{K}_n \) is \( \text{SL}_2(\mathbb{Z}/n)/\{\pm I\} \). If \( n \) is a prime then it suffices to take \( n \geq 23 \).

**Remark 2.** — Theorem 2 is close to optimal in the \( n \)-aspect; cf. Remark 3. However, as in the discussion following Theorem 1, it would be difficult to make Theorem 2 effective.

We will describe our strategy via Müller’s criterion in Section 2, after we establish some notation. To apply this criterion to specializations of \( \Phi_n \), in Section 3 we investigate the algebraic closure of \( \mathbb{Q} \) in the function field defined by \( \Phi_n \), and we study the genus of Riemann surfaces defined by congruence subgroups. In Sections 4 and 5, we develop the technical tools
needed for carrying out the strategy outlined in Section 2. In Section 6, we implement this plan for the generalized Laguerre polynomial after first establishing several geometric properties of the projective plane curve $L_n$ defined by $L_n^{(t)}(x) = 0$. Specifically, let $\iota_n : L_n \to \mathbb{P}_K^1$ be the branched cover defined by the projection-to-$t$ map. Then

(i) $K$ is algebraically closed in the splitting field of $L_n^{(t)}$ over $K(t)$;
(ii) the (geometric) Galois group of $\iota_n$ is $S_n$;
(iii) $L_n^{(t)}(x)$, as a polynomial in $x$, has discriminant which is non-constant in $t$;
(iv) $L_n$ has no affine singular points, and
(v) $\iota_n$ has several “simple” branch points of index close to $n$.

In (v), a simple branch point of index $e$ is one whose fiber consists of a number (possibly 0) of multiplicity one points together with a single ramified point (of multiplicity $e$). The cover defined by the degree $n$ generalized Laguerre polynomial has one simple branch point of every index between 2 and $n$: we use the four of highest index, which suffices in our analysis for all $n \geq 6$. As the calculations in Section 6 will show, the proof of Theorem 1 extends readily to other one-parameter families of polynomials satisfying properties (i)–(v) (as long as their degree is large with respect to the precise form taken by condition (v)). On the other hand, given an arbitrary $\lambda(x,t)$ which is irreducible over $K(t)$, in general we cannot expect all but finitely many of its $K$-specializations to be $K$-irreducible, let alone having the same Galois group as $\lambda(x,t)$ over $K(t)$ — the subvariety $X_\lambda$ mentioned just before the statement of Theorem 1 could, for example, have genus $\leq 1$ giving, for a suitably large $K$, infinitely many specializations $\lambda(x,\alpha)$ with a $K$-linear factor. In Section 7 we analyze this situation further in the case of a degree $n$ simple branched cover, i.e. where every fiber has at least $n - 1$ distinct points. Our result here (Theorem 4) is that almost all $K$-specializations of a simple cover $\pi : Y \to \mathbb{P}_K^1$ of degree $n \geq 7$ possess a $K$-irreducible factor of degree at least $n - 1$; moreover, if $Y$ has genus at least 2, then almost all $K$-specializations are $K$-irreducible and have Galois group $S_n$.

2. Rational specializations

We first establish some notation and hypotheses which will be maintained throughout. Let $K$ be a field of characteristic 0, finitely generated over $\mathbb{Q}$. Fix an algebraic closure $\overline{K}$ of $K$. Denote by $K_0$ the function
field $K(t)$. Fix $\lambda(x, t) \in K[x, t]$ so that $\lambda$ has degree $n > 0$ in $x$ and is irreducible over $K_0$. Then $K_1 := K_0[x]/(\lambda(x, t))$ is a degree $n$ extension of $K_0$. Let $K'/K_0$ be a Galois closure of $K_1/K_0$, and write $G_\lambda = \text{Gal}(K'/K_0)$. By [31, p. 123], the Galois group of $\lambda(x, \alpha)$ over $K$ is a subgroup of $G_\lambda$ for any $\alpha \in K$, and by [31, Prop. 9.2], there are infinitely many $\beta_0 \in K$ for which this Galois group is exactly $G_\lambda$.

From now on, suppose that

(i) $K$ is algebraically closed in $K'/K_0$.

It is a classical fact that every intermediate subfield $E$ of $K'/K_0$ is the function field of a smooth projective curve $X_E$ over $K$, and if $E \subset E'$ are two such subfields, then there exists a $K$-morphism $X_{E'} \to X_E$ of degree $[E' : E]$; for a precise statement over an arbitrary field $K$, see [33, Remark II.2.5]. We write $g(X_E)$ for the genus of $X_E$. By Galois theory, intermediate fields $E$ of $K'/K_0$ are in bijective correspondence with subgroups $\mathcal{E} = \text{Gal}(K'/E)$ of $G_\lambda$.

To simplify the exposition, we abbreviate the phrase

"all but finitely many $\alpha \in K$" by $\alpha \in_{af} K$.

Our approach relies on a classic argument for studying exceptional specializations of $\lambda$ in terms of rational or integral points on certain curves associated to $\lambda$; see, for example, [21, Ch. 9, §1] as well as §5 for more details. For our purposes, a particularly useful version of this argument can be stated as follows.

**Proposition 1.** — Let $K'/K_0$ be as above, and consider a polynomial $f \in K[x, t]$ which is irreducible over $K_0$ but splits completely into linear factors over $K'$. Suppose for every intermediate subfield $E$ of $K'/K_0$ such that $f$ is reducible over $E$, we have $g(X_E) > 1$. Then $f(x, \alpha)$ is $K$-irreducible for $\alpha \in_{af} K$.

**Proof.** — As mentioned above, this is certainly well-known to experts; for a convenient reference see Müller [25, Prop. 4.20]. An alternative method of proof is also indicated in Remark 6 of Subsection 5.2. \qed

For any $\alpha \in K$, the Galois group of $\lambda(x, \alpha)$ over $K$ is a subgroup of $G_\lambda$, and we are interested in finding conditions on $\alpha$ under which $\lambda(x, \alpha)$ is not only $K$-irreducible, but also has Galois group coinciding with the full $G_\lambda$. Here is our strategy: suppose the splitting field of some “test-polynomial” $f(x, t) \in K[x, t]$ is contained in $K'$; then the splitting field of $f(x, \alpha)$ over $K$ is contained in that of $\lambda(x, \alpha)$. So if $f(x, \alpha)$ is $K$-irreducible, then the degree of the splitting field of $\lambda(x, \alpha)$ over $K$ would be divisible by the degree
of \( f(x, \alpha) \). By running through an appropriate collection of \( f \) (e.g. the polynomials \( \Lambda_j \) introduced in 5), we can then hope to show that \( \#G_\lambda \) divides the degree of the splitting field of \( \lambda(x, \alpha) \) over \( K \), whence the Galois group of \( \lambda(x, \alpha) \) over \( K \) must be \( G_\lambda \). To study the irreducibility of the specializations \( f(x, \alpha) \) we use Proposition 1, which reduces the problem to estimating the genus of \( X_E \) as we run through intermediate subfields \( E \) of \( K'/K_0 \).

### 3. Modular equations

By [22, p. 55], the modular polynomial \( \Phi_n(x, j) \in \mathbb{Z}[x, j] \) is irreducible over \( \mathbb{C}(j) \). We now apply the strategy developed in the last section to study specializations of \( \Phi_n \). Denote by \( L_n \) the splitting field of \( \Phi_n \) over \( \mathbb{Q}(t) \). Recall the definition of \( \mathbb{Q}_{p,n} \) and \( \tilde{K}_n \) immediately preceding the statement of Theorem 2.

**Lemma 1.** — *The algebraic closure of \( \mathbb{Q} \) in \( L_n/\mathbb{Q}(t) \) is \( \tilde{\mathbb{Q}}_n \).*

**Proof.** — As a coarse moduli scheme, the open modular curve \( Y_0(n) \) classifies isomorphism classes \( (E \to E') \) of pairs of elliptic curves related via a cyclic \( n \)-isogeny. Over the complex numbers, the map \( (E \to E') \to (j(E), j(E')) \), where \( j(E) \) denotes the \( j \)-invariant of \( E \), is generically injective. Thus the complex points of \( Y_0(n) \) are canonically identified with the complex points of the affine plane curve defined by \( \Phi_n(x, j) = 0 \). Under this identification, the projection-to-\( j \) map from this complex plane curve corresponds precisely to the branched cover \( \pi_0(n) : Y_0(n) \to Y_0(1) \) coming from the inclusion \( \Gamma_0(n) \subset \text{SL}_2(\mathbb{Z}) \). The smallest regular branched cover containing \( \pi_0(n) \) is then the cover \( \pi(n) : Y(n) \to Y(1) = Y_0(1) \) corresponding to the inclusion \( \Gamma(n) \subset \text{SL}_2(\mathbb{Z}) \). In particular, the deck transformation group of \( \pi(n) \) is\(^{(1)}\)

\[
\text{PSL}_2(\mathbb{Z})/(\Gamma(n)/\pm I) \simeq \text{PSL}_2(\mathbb{Z}/n).
\]

It follows that the geometric Galois group of \( \Phi_n \) is \( \text{PSL}_2(\mathbb{Z}/n) \). But Macbeath [24] showed that \( \text{Gal}(L_n/\mathbb{Q}(t)) \simeq \text{PGL}_2(\mathbb{Z}/n) \), so the algebraic closure of \( \mathbb{Q} \) in \( L_n/\mathbb{Q}(t) \) is the compositum of \( \mathbb{Q}(t) \) with a Galois extension \( L(n)/\mathbb{Q} \) with

---

\(^{(1)}\) Given a ring \( R \), we write \( \text{PSL}_2(R) \) for \( \text{SL}_2(R)/\{\pm I\} \), and \( \text{PGL}_2(R) \) for \( \text{GL}_2(R)/\{\text{diagonals}\} \).
Galois group

\[ PGL_2(\mathbb{Z}/n)/PSL_2(\mathbb{Z}/n) \simeq \prod_{p|n} PGL_2(\mathbb{Z}/p^{\epsilon_p})/PSL_2(\mathbb{Z}/p^{\epsilon_p}) \text{ where } p^{\epsilon_p}||n \]

(3.1)

\[ \simeq \prod_{\substack{p|n \\ p \neq 2}} (\mathbb{Z}/2) \times \begin{cases} \mathbb{Z}/2 & \text{if } 8|n \\ \mathbb{Z}/2 & \text{if } 4||n \\ \{1\} & \text{otherwise} \end{cases}. \]

If \( m \mid n \) then \( L_m \subset L_n \), hence \( L(m) \subset L(n) \), so to prove the lemma we are reduced to showing that for any prime power \( p^e > 1 \),

(3.2)

\[ L(p^e) = \mathbb{Q}_{p^e}. \]

For any \( \alpha \in \mathbb{Q} \) and any \( n > 1 \), the splitting field of \( \Phi_n(x, \alpha) \) over \( \mathbb{Q} \) also contains \( L(n) \). Take \( \alpha \in \mathbb{Q} \) to be one of the thirteen \( j \)-invariants over \( \mathbb{Q} \) corresponding to CM elliptic curves over \( \mathbb{Q} \), say \( \alpha = j(\tau) \). Denote by \( k_\alpha/\mathbb{Q} \) the corresponding complex quadratic field. By the ‘First Main Theorem’ of complex multiplication [4, Thm. 11.1], \( k_\alpha(j(n\tau)) \) is the ring class field of \( k_\alpha \) of conductor \( n \), hence \( L(n) \subset k_\alpha(j(n\tau)) \). In particular, \( L(n)/\mathbb{Q} \) is unramified outside of the prime divisors of \( n \) and of the discriminant of \( k_\alpha/\mathbb{Q} \). If \( j(\tau') = \alpha' \in \mathbb{Q} \) is another CM \( j \)-invariant over \( \mathbb{Q} \), then \( L(n) \subset k_\alpha(j(n\tau)) \cap k_{\alpha'}(j(n\tau')) \). We may choose \( \alpha' \) so that \( k_\alpha \) and \( k_{\alpha'} \) have coprime discriminants, whereby \( L(p^e)/\mathbb{Q} \) is unramified outside \( p \). On the other hand, (3.1) says that \( L(p^e)/\mathbb{Q} \) is quadratic if \( p > 2 \) or \( p^e = 4 \), and that it is biquadratic if \( 8 \mid p^e \). Recalling the definition of \( \mathbb{Q}_{p,n} \), we get (3.2) except when \( p^e = 4 \). To treat this remaining case we actually need to determine these ring class fields.

Set \( \omega = \frac{1}{2}(1 + \sqrt{-7}) \), and take \( \alpha = j(\omega) \in \mathbb{Q} \), so \( k_\alpha = \mathbb{Q}(\omega) \). The conductor of the extension \( k_\alpha(\sqrt{-1})/k_\alpha \) clearly divides \( 4\mathbb{Z}[\omega] \). On the other hand, by [4, Thm. 7.24] the ring class field of \( k_\alpha \) of conductor \( 4\mathbb{Z}[\omega] \) is a quadratic extension of \( k_\alpha \), so this ring class field is precisely \( k_\alpha(\sqrt{-1}) \). Recalling (3.1), we see that \( L(4)/\mathbb{Q} \) is a quadratic extension in \( \mathbb{Q}(\omega, \sqrt{-1}) \) unramified outside 2, and (3.2) follows for \( p^e = 4 \). \( \Box \)

Rademacher conjectured that there are only finitely many congruence subgroups with corresponding modular curve of genus zero (cf. [20]). Dennin [7] proved the stronger result that for any integer \( g \), there are at most finitely many \( n \) for which \( PSL_2(\mathbb{Z}/n) \) contains a subgroup of genus \( \leq g \). Cummins and Pauli [5] recently tabulated all such subgroups for \( g \leq 24 \), from which we deduce the following result.
Lemma 2 (Cummins-Pauli). — If $n \geq 53$, then every proper subgroup of $\text{PSL}_2(\mathbb{Z}/n)$ has genus $\geq 2$. If $n$ is a prime, the same conclusion holds for $n \geq 23$. □

Proof of Theorem 2. — Thanks to Lemma 1, the discussion in Section 2 is applicable to $\Phi_n$ over $\tilde{K}_n$ for any number field $K$.

Let $\pi_n$ be a primitive element for the extension $\tilde{K}_nL_n(t)/\tilde{K}_n(t)$, and let $f_n(x, t)$ be the minimal polynomial of $\pi_n$ over $\tilde{K}_n(t)$. Then $f_n$ is irreducible over $\tilde{K}_n(t)$, by construction. So if $n$ is as in Lemma 2, then Proposition 1 and this lemma together imply that for $\alpha \in \tilde{K}_n$, the specializations of $f_n$ and of $\Phi_n$ at $t = \alpha$ are both $\tilde{K}_n$-irreducible. If we write $F_n(\alpha)$ for the splitting field of $\Phi_n(x, \alpha)$ over $\tilde{K}_n$, then that means $[F_n(\alpha) : \tilde{K}_n]$ is divisible by $\deg f_n = [\tilde{K}_nL_n(t) : \tilde{K}_n(t)] = \# \text{PSL}_2(\mathbb{Z}/n)$, and Theorem 2 follows. □

Remark 3. — The fact that every non-trivial intermediate subfield of $\tilde{K}_nL_n(t)/\tilde{K}_n(t)$ has genus $\geq 2$ for $n \geq 53$ significantly simplifies our search for the ‘test polynomial’ $f$ in Proposition 1. The modular curve $X_0(n)$ has genus $\leq 1$ for $n \leq 21$ and for $n \in \{24, 25, 27, 32, 36, 49\}$, so by the discussion immediately preceding Theorem 1, for these $n$ the modular equation has infinitely many reducible specializations over suitable $K$. To analyze the remaining values of $n \leq 52$ we could search for test polynomials $f$ which remain irreducible over intermediate subfields of genus $\leq 1$. We will not pursue this issue here, but in Section 5 we will study the same problem for specializations of $S_n$-extensions by using a family of $[\frac{1}{2}(n-1)]$ test polynomials $\Lambda_j(x, t)$.

4. A Riemann-Hurwitz estimate

We now return to the general setup in Section 2. To apply Proposition 1, we need to be able to estimate the genus of certain intermediate subfields of $K'/K_0$. To do that we will apply the Riemann-Hurwitz formula to the cover $\xi_E : X_E \to \mathbb{P}^1_K$ corresponding to the field inclusion $K_0 \subset E$. Since we do not have any explicit model for $X_E$, we will take an algebraic approach. Thanks to hypothesis (i) in Section 2, in order to determine the ramification of the geometric cover $X' \to \mathbb{P}^1_K$ it suffices to determine the algebraic ramification behavior of integral extensions of Dedekind domains corresponding to this geometric cover.

Denote by $B_\lambda \subset \mathbb{P}^1_K$ the branch locus of the projection-to-$t$ map for $\lambda$. Then $\xi_E$ is unramified outside $B_\lambda$. Fix affine open sets on $X_E$ and $X'$ which
contain every fiber of $\xi_E$ and $X' \to \mathbb{P}^1_K$ above $B_\lambda$, and denote by $\mathcal{O}_E$ and $\mathcal{O}'$ their respective affine coordinate rings. Write $\mathcal{O}_0$ for the affine coordinate ring of the affine line in $\mathbb{P}^1_K$. Let $m_\nu$ (or just $m$ if $\nu$ is fixed) be the maximal ideal in $\mathcal{O}_0$ corresponding to a given $\nu \in B_\lambda$. We let $e_\nu = e(M/m)$ be the ramification index of $M$ in the Galois cover $K'/K_0$, where $M$ is an arbitrary prime of $\mathcal{O}'$ dividing $m\mathcal{O}'$.

**Definition 1.** — (a) For a positive integer $\delta$ and a branch point $\nu \in B_\lambda$ corresponding to an ideal $m$ of $\mathcal{O}_0$, let

$$c_\delta(\nu) = c_\delta(m) = \sum_{\substack{n \mid m\mathcal{O}_E \\; e(n/m) = \delta}} f(n/m),$$

be the sum of the residual degrees of distinct $\mathcal{O}_E$-primes $n$ of ramification index $\delta$ over $m$.

(b) For $\nu \in B_\lambda$ corresponding to an ideal $m$ of $\mathcal{O}_0$, let

$$\Delta(\nu) = \Delta(m) = \sum_{n \mid m\mathcal{O}_E} \left( e(n/m) - 1 \right) f(n/m)$$

be the $\nu$-component of the discriminant of $E/K_0$.

(c) For an integer $e > 1$, let $d(e)$ be the least prime divisor of $e$.

**Lemma 3.** — With the notation and hypotheses as in Section 2, if $E$ is an intermediate field of $K'/K_0$ corresponding to a subgroup

$$\mathcal{E} = \text{Gal}(K'/E)$$

of $G_\lambda = \text{Gal}(K'/K_0)$, and $V$ is any subset of $B_\lambda$, then

$$g(X_E) \geq 1 + \frac{[G : \mathcal{E}]}{2} \left( -2 + \sum_{\nu \in V} \left( 1 - \frac{1}{d(e_\nu)} \right) \right) - \frac{1}{2} \sum_{\nu \in V} c_1(\nu) \left( 1 - \frac{1}{d(e_\nu)} \right).$$

**Proof.** — First, note that

$$\sum_{1 \leq \delta \leq d(e_\nu)} c_\delta(\nu) \delta = [E : K_0] = [G_\lambda : \mathcal{E}].$$
For each $\nu \in B_{\lambda}$, we have from Definition 1,
\[
\Delta(\nu) = \sum_{1 \leq \delta | e_{\nu}} c_{\delta}(\nu)(\delta - 1) = \sum_{1 < \delta | e_{\nu}} c_{\delta}(\nu) \left(1 - \frac{1}{\delta}\right)\delta \\
\geq \left(1 - \frac{1}{d(e_{\nu})}\right) \sum_{1 < \delta | e_{\nu}} c_{\delta}(\nu)\delta \\
\geq \left(1 - \frac{1}{d(e_{\nu})}\right) \sum_{1 \leq \delta | e_{\nu}} c_{\delta}(\nu)\delta - \left(1 - \frac{1}{d(e_{\nu})}\right)c_{1}(\nu) \\
\geq [G_{\lambda} : \mathcal{E}]\left(1 - \frac{1}{d(e_{\nu})}\right) - c_{1}(\nu)\left(1 - \frac{1}{d(e_{\nu})}\right)
\]
(4.3) by (4.2).

By Riemann-Hurwitz for $E/K_0$, [26, Theorem 7.16], we have
\[
g(X_{E}) - 1 = [E : K_0](0 - 1) + \frac{1}{2} \sum_{\nu \in B_{\lambda}} \Delta(\nu).
\]
Since $\Delta(\nu) > 0$, we have, for any subset $V \subseteq B_{\lambda}$,
\[
g(X_{E}) \geq 1 - [G_{\lambda} : \mathcal{E}] + \frac{1}{2} \sum_{\nu \in V} \Delta(\nu) \\
\geq 1 + \frac{[G_{\lambda} : \mathcal{E}]}{2} \left(-2 + \sum_{\nu \in V} \left(1 - \frac{1}{d(e_{\nu})}\right)\right) - \frac{1}{2} \sum_{\nu \in V} c_{1}(\nu)\left(1 - \frac{1}{d(e_{\nu})}\right)
\]
by (4.3).

\textbf{Remark 4.} — Note that the bound (4.1) is useful only when $c_{1}(\nu)$ is fairly small for all $\nu \in V$, so in using (4.1), it is often useful to take $V$ to be a proper subset of $B_{\lambda}$. Moreover, the inequality (4.1) is in fact strict if $V$ is a proper subset of $B_{\lambda}$ since $\Delta(\nu) > 0$ for $\nu \in V$.

In view of Proposition 1, our task will be to show that the right hand side of (4.1) is $> 1$ when a given $f(x, t) \in K[x, t]$ is reducible over $E$. For our application to generalized Laguerre polynomials, we will achieve this by taking $V$ to be an appropriately small subset of $B_{\lambda}$.

We now turn to the task of bounding $c_{1} = c_{1}(\nu)$ from above, where, for the remainder of this section, $\nu \in B_{\lambda}$ is a fixed branch point, with corresponding ideal $m = m_{\nu}$ of $\mathcal{O}_0$. Fix also a prime $\mathfrak{m} \subset \mathcal{O}'$ lying over $m$, with corresponding decomposition group $D = \{\sigma \in G : \mathfrak{m}^\sigma = \mathfrak{m}\}$, and inertia group $I = I(\mathfrak{m}/m)$. Let $T$ be a subset of $G = G_{\lambda} = \text{Gal}(K'/K_0)$ such that
\[
G = \prod_{\tau \in T} \mathcal{E}_{\tau}D
\]
(4.4)
With the notation introduced above, the decomposition of $G$ into disjoint double cosets, where $\mathcal{E} = \text{Gal}(K'/E)$ is the subgroup fixing $E$.

As is clear from Lemma 3, it will be important to keep track of the primes $\mathfrak{n}$ of $\mathcal{O}_E$ dividing $\mathfrak{m}$ and especially their ramification indices $e(\mathfrak{n}/\mathfrak{m})$. That these can be described nicely in terms of the double coset decomposition (4.4) is a useful fact (we learned from Tate) for which we were not able to find a suitable reference, so we give the details. For each $\sigma \in G$, let $\mathfrak{n}_\sigma$ be the prime $\mathfrak{M}^\sigma \cap \mathcal{O}_E$ of $\mathcal{O}_E$ lying under $\mathfrak{M}^\sigma$. Let $I_\sigma \subseteq D_\sigma$ be the inertia and decomposition groups of $\mathfrak{M}^\sigma/\mathfrak{m}$, respectively. They satisfy $D_\sigma = \sigma D \sigma^{-1}$ and $I_\sigma = \sigma I \sigma^{-1}$. In the extension $K'/E$, the inertia and decomposition groups for $\mathfrak{M}^\sigma/\mathfrak{n}_\sigma$ are simply $I_\sigma \cap \mathcal{E}$ and $D_\sigma \cap \mathcal{E}$, respectively. For the ramification indices of $\mathfrak{M}/\mathfrak{m}, \mathfrak{M}/\mathfrak{n}_\sigma$, and $\mathfrak{n}_\sigma/\mathfrak{m}$, let us put

$$e = e(\mathfrak{M}/\mathfrak{m}), \quad e'_\sigma = e(\mathfrak{M}/\mathfrak{n}_\sigma), \quad e_\sigma = e(\mathfrak{n}_\sigma/\mathfrak{m}),$$

and similarly for the residual degrees, we put

$$f = f(\mathfrak{M}/\mathfrak{m}), \quad f'_\sigma = f(\mathfrak{M}/\mathfrak{n}_\sigma), \quad f_\sigma = f(\mathfrak{n}_\sigma/\mathfrak{m}).$$

By multiplicativity in towers for these invariants, we have

$$e_\sigma e'_\sigma = e, \quad f_\sigma f'_\sigma = f. \quad (4.5)$$

**Lemma 4.** — With the notation introduced above,

(a) The distinct primes of $\mathcal{O}_E$ dividing $\mathfrak{m}$ are those induced by $\mathfrak{M}^\tau$ for $\tau \in T$. In other words, we have $\mathfrak{n}_\sigma = \mathfrak{n}_{\sigma'}$ if and only if $\mathcal{E} \sigma D = \mathcal{E} \sigma' D$.

(b) For $\sigma \in G$, we have

$$e_\sigma f_\sigma = [\sigma D \sigma^{-1} : \mathcal{E} \cap \sigma D \sigma^{-1}], \quad e_\sigma = [\sigma I \sigma^{-1} : \mathcal{E} \cap \sigma I \sigma^{-1}].$$

**Proof.** — Let $w$ be the valuation of $\mathcal{O}'$ corresponding to $\mathfrak{M}$. For $\alpha \in \mathcal{O}'$, we have $|\alpha|_{\sigma w} = |\sigma^{-1} \alpha|_w$. If $\mathcal{E} \sigma D = \mathcal{E} \sigma' D$, we can write $\sigma' = h \sigma g$, with $h \in \mathcal{E}, g \in D$. For $\alpha \in \mathcal{O}_E$, we compute

$$|\alpha|_{\sigma' w} = |\alpha|_{h \sigma g w} = |\alpha|_{h \sigma w} = |h^{-1} \alpha|_{\sigma w} = |\alpha|_{\sigma w}.$$

Thus, $\sigma w$ and $\sigma' w$ induce the same valuation on $\mathcal{O}_E$, i.e. $\mathfrak{n}_\sigma = \mathfrak{n}_{\sigma'}$. Conversely, suppose $\mathfrak{n}_\sigma = \mathfrak{n}_{\sigma'}$, i.e. the set of primes of $\mathcal{O}'$ lying over $\mathfrak{n}_\sigma$ includes $\mathfrak{M}^\sigma$ as well as $\mathfrak{M}^{\sigma'}$. Since $\mathcal{E} = \text{Gal}(K'/E)$ acts transitively on this set, there exists $h \in \mathcal{E}$ such that $\mathfrak{M}^{h \sigma'} = \mathfrak{M}^{\sigma'}$, i.e. $\sigma^{-1} h \sigma' \in D$. Therefore, $\mathcal{E} \sigma D = \mathcal{E} \sigma' D$. This proves (a). We have $e f = \# I_\sigma f = \# D_\sigma$ and $e'_\sigma f'_\sigma = \# (I_\sigma \cap \mathcal{E}) f'_\sigma = \# (D_\sigma \cap \mathcal{E})$, so we get (b) by multiplicativity in towers (4.5). \qed
Define
\[ Y = \{ \sigma \in G : \sigma I \sigma^{-1} \subset \mathcal{E} \}. \]
For the application to Riemann-Hurwitz, we’ll need to estimate \( c_1 \). We proceed as follows.

**Lemma 5.** — If \( a \in Y \), then \( \{ b \in Y : \mathcal{E}aI = \mathcal{E}bI \} = \mathcal{E}a \). We have \( c_1 = \#Y/\#\mathcal{E} \).

**Proof.** — We first make a remark that simplifies the calculation. Note that if we compose our fields \( K_0 \subset E \subset K' \) with a finite extension \( \tilde{K} \) of the constant field \( K \) that splits \( \mathfrak{m} \), then \( c_\delta(m) \) remains unchanged, since each prime \( n_\sigma \) of \( E \) of residual degree \( f_\sigma \) splits in \( E \tilde{K} \) into \( f_\sigma \) primes of residual degree 1 with the same inertia group \( I_\sigma \cap \mathcal{E} \). In fact, the genus calculation we are performing is a purely geometric one, so we could have simply assumed from the outset that the constant field \( K \) is algebraically closed.

Either way, we take \( \mathfrak{m}/m \) as above and assume without loss of generality, that \( f(\mathfrak{m}/m) = 1 \), i.e. \( I = D \). By Lemma 4, for any \( \sigma \in G \), \( e(n_\sigma/m) = 1 \) if and only if \( \sigma I \sigma^{-1} \subset \mathcal{E} \). Thus
\[
(4.6) \quad c_1 = \#\{ \mathcal{E}\sigma I : \sigma I \sigma^{-1} \subset \mathcal{E} \}.
\]

Note that \( \mathcal{E}aI = \mathcal{E}bI \) if and only if \( b \in \mathcal{E}aI \). Suppose \( b \in Y \) and \( b \in \mathcal{E}aI \). Then \( ba^{-1} \in \mathcal{E}aIa^{-1} \subset \mathcal{E} \), hence \( b \in \mathcal{E}a \). Conversely, suppose \( b = ha \) with \( h \in \mathcal{E} \). Then
\[
bIb^{-1} = haIa^{-1}h^{-1} \subset h\mathcal{E}h^{-1} = \mathcal{E}
\]
so \( b \in Y \). Finally, clearly \( \mathcal{E}a \subset \mathcal{E}aI \) so \( b \in \mathcal{E}a \) implies \( b \in \mathcal{E}aI \). Therefore, \( Y \) is a union of (right) cosets of \( \mathcal{E} \), and the number of distinct double cosets \( \mathcal{E}aI \) with \( a \in Y \) is exactly \( \#Y/\#\mathcal{E} \). This completes the proof by (4.6).

Since we are working with function fields of characteristic 0, all ramification is tame, so the inertia group \( I \) is cyclic. We now specialize to the case where \( G = S_n \), and \( I \) is generated by a cycle (under its natural action on the roots of \( \lambda \)). Of course, if \( \#I \) is greater than \( \frac{1}{2}n \), the latter condition holds automatically.

**Lemma 6.** — If \( \text{Gal}(K'/K_0) = S_n \) and \( I \) is generated by an \( m \)-cycle, then
\[
(4.7) \quad c_1 = \frac{\text{(number of } m\text{-cycles in } \mathcal{E})}{\#\mathcal{E}} \times m(n-m)!
\]
\[
(4.8) \quad < m(n-m)!
\]
Proof. — Just as in the proof of the preceding lemma, we may assume that \( I = D \). Let \( J = \{ sI s^{-1} \subset E : s \in G \} \) be the set of subgroups of \( E \) which are \( G \)-conjugate to \( I \). Then

\[
\# Y = \sum_{I' \in J} \# \{ s \in G : sI' s^{-1} = I' \}.
\]

Any two \( m \)-cycles in \( S_n \) are \( S_n \)-conjugate, so

\[
\# J = \text{number of cyclic subgroups of } E
\]

\[
= \frac{\text{number of } m \text{-cycles in } E}{\varphi(m)}.
\]

There are \( n!/(m(n - m)!) \) \( m \)-cycles in \( S_n \), so for any \( S_n \)-conjugate \( I' \subset E \) of \( I \),

\[
\# \{ s \in S_n : sI' s^{-1} = I' \} = \frac{n!}{\# \text{orbits}_{S_n}(I')} = \frac{n!}{\frac{n!}{m(n-m)!}/\varphi(m)} = m\varphi(m)(n - m)!
\]

The proof is complete once we combine (4.9)–(4.12) with Lemma 5. \( \square \)

We end this section with an elementary criterion which guarantees the hypothesis of Lemma 6 (on inertia being generated by a cycle) to hold; the criterion will be easily verified for the generalized Laguerre polynomial at all its branch points.

Recall that \( K_1/K_0 \) is a root field for \( \lambda \), i.e. \( K_1 \simeq K_0[x]/(\lambda) \).

Definition 2. — Let \( \nu \in B_\lambda \) be a branch point of \( \lambda \), with corresponding maximal ideal \( \mathfrak{m} \subset \mathcal{O}_0 \). Let \( e > 1 \) be an integer. We say that \( \nu \) (or \( \mathfrak{m} \)) is simple of index \( e \) for \( \lambda \) if

\[
m\mathcal{O}_{K_1} = n_0 n_1 \cdots n_s,
\]

where \( n_0, \ldots, n_s \) are pairwise distinct primes of \( \mathcal{O}_{K_1} \); in other words, in \( \mathcal{O}_{K_1} \), there is a unique prime dividing \( m\mathcal{O}_{K_1} \), with non-trivial ramification index (equal to \( e \)).

Lemma 7. — Suppose \( G = \text{Gal}(K'/K_0) = S_n \). Let \( \mathfrak{m} \subset \mathcal{O}_0 \) be a maximal ideal corresponding to a branch point \( \nu \in B_\lambda \), which is simple of index \( e > 1 \). Then, for any \( \mathfrak{M} \subset \mathcal{O}' \) lying above \( \mathfrak{m} \), the inertia group \( I = I(\mathfrak{M}/\mathfrak{m}) \) has order \( e \) and is generated by a cycle of length \( e \).
Proof. — Let $\mathcal{E} = \text{Gal}(K'/K_1)$. The index $n$ subgroups in $S_n$ are stabilizers of any one of the $n$ letters. By reordering the roots if needed, we can identify $\mathcal{E} \simeq S_{n-1}$ with the stabilizer of the letter $n$. Every element in $S_n$ is a product of disjoint, non-trivial cycles. This decomposition is unique once a labelling is fixed, and two elements in $S_n$ are conjugate if and only if they decompose into the same number of cycles of each length.

Returning to the proof of the lemma, suppose $\mathcal{M}$ is a prime of $\mathcal{O}'$ whose restriction $\mathcal{M} \cap \mathcal{O}_{K_1}$ is the unique prime $n$ of $\mathcal{O}_{K_1}$ of ramification index $e > 1$ over $\mathfrak{m}$. Let $I = I(\mathcal{M}/\mathfrak{m})$. We may assume, as in the preceding lemmas, that composing with a suitable finite extension of $K$, $\mathcal{M}/\mathfrak{m}$ has degree 1, i.e. $I = D$ (this disturbs neither the identification $G \simeq S_n$ nor the embedding $I \hookrightarrow G$).

Let $\gamma$ be a generator of the cyclic group $I$. Write $\gamma = \gamma_1 \cdots \gamma_r$ for its decomposition into disjoint, possibly trivial, cycles. Since the $\gamma_i$ pairwise commute, we may assume that the letter $n$ occurs in the cycle $\gamma_1$. For $1 \leq i \leq r$, let $a_i = \text{ord}(\gamma_i) \geq 1$, and let $a = \min\{m \geq 1 : \gamma^m \in \mathcal{E}\}$. On the one hand, $\gamma^a$ generates $I \cap \mathcal{E}$, and, on the other hand, we have $a = a_1$ (recalling our convention that $\mathcal{E}$ is the stabilizer of the letter $n$).

By Lemma 4, $e(\mathfrak{n}/\mathfrak{m}) = \#[I/(I \cap \mathcal{E})] = \#([\gamma]/[\gamma^a]) = a$, thus $\gamma_1$ has order $a = a_1 = e > 1$, since we took $\mathfrak{n}$ to be the unique prime of ramification index $e > 1$ over $\mathfrak{m}$.

It remains to show that the cycles $\gamma_2, \ldots, \gamma_r$ are trivial, i.e. $a_i = 1$ for $i > 1$. We proceed by contradiction. If $a_2 > 1$, say, then, there exists $\sigma \in G$ such that $\sigma \gamma_2 \sigma^{-1}$ is a cycle acting non-trivially on the letter $n$. Then, as before, $e(\mathfrak{n}_\sigma/\mathfrak{m}) = a_2 > 1$, so we get $a_2 = e$ and $\mathfrak{n}_\sigma = \mathfrak{n}$ by the assumption on the simplicity of the ramification. By Lemma 4, therefore, $\sigma \in \mathcal{E}I$, say $\sigma = \eta \theta$ with $\eta \in \mathcal{E}$ and $\theta \in I$. Letting $x' = \sigma x \sigma^{-1}$ for $x \in G$, we have $\gamma' = \gamma_1' \gamma_2' \cdots \gamma_r'$ is the decomposition of $\gamma'$ into disjoint cycles since conjugation preserves cycle structure. But we claim that $\gamma_1'$ and $\gamma_2'$ are not disjoint, as they both act non-trivially on the letter $n$. To see this, note that $\theta = \gamma^b$ for some integer $b$, so $\theta \gamma_i \theta^{-1} = \gamma_i$ for $i = 1, \ldots, r$. On the other hand, since $\eta \in \mathcal{E}$, it fixes $n$, so $\gamma'_1 = \eta \gamma_1 \eta^{-1}$ and $\gamma'_2 = \eta \gamma_2 \eta^{-1}$ are both $e$-cycles that act non-trivially on $n$, hence are not disjoint. This contradiction shows that $\gamma_2, \ldots, \gamma_r$ are all trivial, so $I = \langle \gamma_1 \rangle$ is generated by an $e$-cycle, hence has order $e$. $\square$
5. Specializations of $S_n$-covers

In this section, we develop a strategy for applying Proposition 1 to a geometric $S_n$-cover. Namely, starting with an $S_n$-extension of function fields $K'/K_0$ as in Section 2, in Subsection 5.1 we construct a family of polynomials $\Lambda_j(x, t) \in K[x, t]$ with splitting field contained in $K'$ (to which we will later apply Proposition 1). In 5.2, we will give a geometric interpretation in terms of fiber products for the curves corresponding to these $\Lambda_j$: their $K$-rational points correspond precisely to the $K$-rational degree $j$ factors of $\lambda$. We will use this interpretation in the proof of Theorem 1 for controlling the genus of subfields of $K'$ cut out by a subgroup contained in $A_n$, and also for the study of simple branched covers in the final section. A reader who is interested in a proof of Theorem 1 for $n \geq 10$ only, can skip 5.2 entirely, as it will enter the proof only for $6 \leq n \leq 9$.

5.1. Distinguished subfields in $S_n$-extensions

Let $\lambda(x, t)$ and $K'/K_0$ be as in Section 2; in particular, recall the regularity hypothesis (i) introduced there. Suppose further that

(ii) $G_\lambda \simeq S_n$, and

(iii) $\lambda$, as a polynomial in $x$, has discriminant which is non-constant in $t$.

These two conditions actually recover the regularity of the cover, at least when $n$ is not too small.

**Lemma 8.** — Suppose $n \geq 5$. Then

(a) $K$ is algebraically closed in $K'/K_0$, and

(b) $K'/K_0$ has a unique Galois subfield. This subfield is quadratic over $K_0$.

**Proof.** — Fix an algebraic closure $\overline{K}$ of $K$. Then $\overline{K} \cap K'$ is a Galois subfield of the $S_n$-extension $K'/K_0$. Since $n \geq 5$, the only non-trivial Galois subfield in $K'/K_0$ is the unique quadratic subfield generated by the square-root of the discriminant (with respect to $x$) of $\lambda(x, t)$. Invoke the discriminant condition on $\lambda$ and we are done. □

The following result is standard.

**Lemma 9.** — Let $X/K$ be a smooth projective curve, and let $\xi : X \to \mathbb{P}^1_K$ be a non-constant $K$-morphism. Then $X$ is $K$-birational to a plane curve $G(x, t) = 0$ such that $\xi$ is the projection-to-$t$ map. □
We now describe a distinguished collection of subfields in \( K'/K_0 \). Fix a labelling of the roots of \( \lambda(x, t) \) over \( K_0 \), giving an identification of \( G_\lambda \) with the symmetric group \( S_n \). For \( 1 \leq j < n \), write \( S_{n,j} \) for the subgroup \( S_j \times S_{n-j} \subset S_n \), where \( S_j \) permutes the first \( j \) roots, and \( S_{n-j} \), the remaining \( n-j \) roots. Denote by

- \( K_j \) the subfield of \( K'/K_0 \) fixed by \( S_{n,j} \),
- \( X_j \) the associated smooth projective curve over \( K \), and
- \( \tilde{\phi}_{n,j} : X_j \to \mathbb{P}^1_K \) the \( K \)-branched cover corresponding to the extension \( K_j/K_0 \).

Lemma 9 furnishes a \( K \)-birational map taking \( X_j \) to a plane curve \( \Lambda_j(x, t) = 0 \) which is smooth above \( t = \beta_0 \), and such that \( \tilde{\phi}_{n,j} \) is the projection-to-\( t \) map. Clearly we can take \( \Lambda_1 = \lambda \) and do so. Since \( X_j \) is smooth, it is absolutely irreducible, hence so is \( \Lambda_j(x, t) \). Thus we can apply Proposition 1 to \( \Lambda_j \).

**Lemma 10.** — Fix positive integers \( n, j \) satisfying \( n \geq 5 \) and \( j \in [1, \frac{1}{2} n] \). Suppose for every intermediate subfield \( E \) of \( K'/K_0 \) over which \( \Lambda_j(x, t) \) is reducible, we have \( g(X_E) > 1 \). Then for \( \alpha \in_{af} K \), the specialization \( \lambda(x, \alpha) \) is \( K \)-irreducible, and its splitting field has degree divisible by \( \binom{n}{j} \).

**Proof.** — As \( \deg \tilde{\phi}_{n,j} = [K_j : K_0] = \#S_n/\#S_{n,j} = \binom{n}{j} \geq n \), and \( n \geq 5 \), Lemma 8 (b) says that \( K'/K_0 \) is the Galois closure of \( K_j \); equivalently, \( K'/K_0 \) is the splitting field of \( \Lambda_j(x, t) \) over \( K_0 \). But \( K' \) is the splitting field of \( \lambda(x, t) = \Lambda_1(x, t) \) over \( K_0 \), so by Proposition 1, for \( \alpha \in_{af} K \) the splitting field of \( \lambda(x, \alpha) \) contains the roots of \( \Lambda_j(x, \alpha) \), and we are done. \( \square \)

For the proof of Theorem 1, we will employ the following application of Proposition 1.

**Theorem 3.** — Suppose \( n \geq 7 \) and \( \Lambda_j(x, t) \) satisfies the hypothesis in Lemma 10 for each integer \( j \in [1, \frac{1}{2} n] \). Then for \( \alpha \in_{af} K \), the specialization \( \lambda(x, \alpha) \) is \( K \)-irreducible and has Galois group containing \( A_n \).

**Proof.** — First, recall that \( \Lambda_1 = \lambda \). By Lemma 10, \( \lambda(x, \alpha) \) is \( K \)-irreducible for \( \alpha \in_{af} K \), hence its Galois group is a transitive subgroup of \( S_n \). If \( n \geq 8 \), then there exists a prime \( q \) with \( \frac{1}{2} n < q < n - 2 \) [27, p. 370]. Necessarily \( q \) divides \( \binom{n}{k} \) for some \( 1 < k < \frac{1}{2} n \), so by Lemma 10, for \( \alpha \in_{af} K \) the specialization \( \lambda(x, \alpha) \) is \( K \)-irreducible, and \( q \) divides the degree of its splitting field over \( K \). That means the Galois group of such a \( \lambda(x, \alpha) \) is a transitive subgroup of \( S_n \) and has order divisible by \( q \); a theorem of Jordan [18, Thm. 5.6.2 and 5.7.2] then implies that this Galois group contains \( A_n \).
For \( n = 7 \), Lemma 10 implies that for \( \alpha \in_{af} K \), the Galois group of \( \lambda(x, \alpha) \) is a transitive subgroup of \( S_7 \) of size divisible by \( \text{LCM}\left(\left(\frac{7}{2}\right), \left(\frac{7}{3}\right)\right) = 105 \). By the classification of transitive subgroups of \( S_7 \) [8, p. 60] it follows that this Galois group contains \( A_7 \). □

Remark 5. — After we completed the manuscript, Edixhoven informed us that by [19, Thm. XII.4.3] and the classification of finite simple groups (which verifies the Schreier hypothesis, cf. [8, App. A]), any \( k \)-fold transitive group of \( S_n \) for \( k \geq 6 \) is either \( A_n \) or \( S_n \). It follows that in Theorem 3 it suffices to take \( 1 \leq j \leq 7 \). However, this improved range for \( j \) does not simplify our subsequent genus calculation, so we will stick to Theorem 3 in its present form.

5.2. Interpretation in terms of fiber products

We continue with the notation of the previous subsection and assume properties (i)-(iii) are satisfied. Fix a labelling \( \lambda_1, \ldots, \lambda_n \) of the roots of \( \lambda = \Lambda_1 \) in \( K' \), and let \( \Sigma = \Sigma_1 = \{\lambda_1, \ldots, \lambda_n\} \). For an integer \( j \in [1, n-1] \), let \( \Sigma_j \) be the set of roots of \( \Lambda_j \) in \( K' \), and let \( \Sigma^{(j)} \) be the set of “\( j \)-subsets” of \( \Sigma \) (i.e. those of cardinality \( j \)). Recall that \( \Lambda_j \) splits into linear factors over \( K' \), hence \( \#\Sigma_j = \#\Sigma^{(j)} = \binom{n}{j} \). Each of these sets carries a natural action of \( \text{Gal}(K'/K_0) \cong S_n \).

**Lemma 11.** — For each \( j \in [1, n-1] \), there is a bijective correspondence between \( \Sigma_j \) and \( \Sigma^{(j)} \) which respects the natural action of \( \text{Gal}(K'/K_0) \) on these sets.

Before proving Lemma 11, let us state two applications of it that we shall need.

**Proposition 2.** — For \( \alpha \in K \), the \( K \)-rational roots of \( \Lambda_j(x, \alpha) \) are in one-to-one correspondence with the \( K \)-rational degree \( j \) factors of \( \lambda(x, \alpha) \).

**Proof.** — The \( K \)-rational linear factors of \( \Lambda_j(x, \alpha) \) are in one-to-one correspondence with the fixed points of \( G_\lambda \) in its action on \( \Sigma^{(j)} \). By the lemma, these are in one-to-one correspondence with the \( G_\lambda \)-invariant subsets of \( \Sigma \) of size \( j \). The roots of a \( K \)-rational degree \( j \) factor of \( \lambda(x, \alpha) \) clearly form such a subset, and conversely, a \( G_\lambda \)-invariant \( T \in \Sigma_j \) gives the \( K \)-rational degree \( j \) factor \( \prod_{\theta \in T} (x - \theta) \) of \( \lambda \). □
Remark 6. — Proposition 2 lends some perspective on Proposition 1. Namely, $\lambda$ has a degree $j$ $E$-rational factor, for some $j$ in the range $1 \leq j \leq n - 1$ and some intermediate field $K_0 \subseteq E \subseteq K'$, if and only if $\Lambda_j$ has a root in $E$, i.e. if and only if $E$ contains (a conjugate of) $K_j$. Thus the hypothesis of Proposition 1, namely that $g(X_E) \geq 2$ for every $E$ over which $\lambda$ is reducible is equivalent to the hypothesis that $g(X_j) \geq 2$ for $1 \leq j \leq n - 1$. One then obtains Proposition 1 by applying Proposition 2 in conjunction with Faltings’ Theorem.

Proposition 3. — Suppose $1 \leq j \leq n - 1$. Then $\Lambda_j(x, t)$ is irreducible over the subfield of $K'/K_0$ fixed by $A_n$.

Proof. — Since the group $A_n$ is $(n - 2)$-transitive, if $2 \leq j \leq n - 2$ then $A_n$, as a subgroup of the group of permutations on the set $\Sigma$, acts transitively on the set $\Sigma^{(j)}$. Thanks to Lemma 11, $A_n$, as a subgroup of $\text{Gal}(K'/K_0)$, then acts transitively on the set of roots of $\Lambda_j$ in $K'$, establishing the proposition for this range of $j$.

Write $F$ for the fixed field of $K'/K_0$ by $A_n$. If $\Lambda_1$ is reducible over $F$, then $\text{Gal}(K'/F)$ is contained in $S_\ell \times S_{n-\ell}$ for some $1 \leq \ell \leq n - 1$. Since $F/K_0$ is quadratic, $\# \text{Gal}(K'/K_0) \leq 2 \cdot \# S_\ell \cdot \# S_{n-\ell} < \# S_n$, a contradiction. Thus $\Lambda_1$ is irreducible over $F$. Thanks to Lemma 11, that means $A_n$, as a subgroup of the group of permutations of $\Sigma$, acts transitively on $\Sigma^{(1)}$, hence also on $\Sigma^{(n-1)}$. Applying Lemma 11 again, we see that $\Lambda_{n-1}$ is irreducible over $F$, as desired. $\square$

We now verify Lemma 11 via a fiber product construction. The lemma and the construction are probably well-known, but we cannot locate a reference for either one so we give the details here. We begin with a general setup. Recall that $K$ is a field of characteristic 0.

Let $\varphi^n_K$ denote the set of equivalence classes of non-zero, degree $\leq n$ polynomials in $K[x]$, where two polynomials are identified if they are $K^\times$-multiples of each other. We have a natural bijection between $\varphi^n_K$ and the set of $K$-rational points $\mathbb{P}^n_K(K)$ of projective $n$-space, via

$$a_0x^n + a_1x^{n-1} + \cdots + a_n \mapsto [a_0 : \cdots : a_n].$$

In light of this, to give a polynomial $\lambda(x, t) \in K[x, t]$ which is non-constant and of degree $\leq n$ in $x$ is to give a non-constant $K$-morphism $\Lambda : \mathbb{P}^1_K \to \mathbb{P}^n_K$. Also, for every $1 \leq j < n$ the multiplication map $\varphi^j_K \times \varphi^{n-j}_K \to \varphi^n_K$ gives
rise to a $K$-morphism $\phi_{n,j} : \mathbb{P}^j_K \times \mathbb{P}^{n-j}_K \to \mathbb{P}^n_K$, whence a pull-back diagram

$$
\begin{array}{ccc}
X & \overset{\Lambda(j)}{\longrightarrow} & \mathbb{P}^j_K \times \mathbb{P}^{n-j}_K \\
\phi_{n,j} \downarrow & & \downarrow \\
\mathbb{P}^1_K & \overset{\Lambda}{\longrightarrow} & \mathbb{P}^n_K.
\end{array}
$$

(5.1)

Denote by $\phi_n : (\mathbb{P}^1_K)^n \to \mathbb{P}^n_K$ the $K$-morphism corresponding to the $n$-fold multiplication map $(\wp^1_K)^n \to \wp^n_K$. Then we have an analogous pull-back diagram

$$
\begin{array}{ccc}
\overline{X} & \overset{\overline{\Lambda}}{\longrightarrow} & (\mathbb{P}^1_K)^n \\
\overline{\phi}_n \downarrow & & \downarrow \phi_n \\
\mathbb{P}^1_K & \overset{\Lambda}{\longrightarrow} & \mathbb{P}^n_K.
\end{array}
$$

(5.2)

Any permutation of the $n$-coordinates of the points of $(\mathbb{P}^1_K)^n$ is a $K$-morphism which is compatible with $\phi_n$. Clearly $\deg \phi_n = n!$, so $\phi_n$ is a regular branched cover with deck transformation group $S_n$.

Suppose $\Lambda$ corresponds to a separable, degree $n$ polynomial $\lambda$ over $K_0 = K(t)$. Then the fiber of $\overline{\phi}_n$ over the generic point of $\mathbb{P}^1_K$ consists of $n!$ pairwise distinct, ordered $n$-tuples of the roots of $\lambda$ over $K_0$. Every element of the Galois group $G_\lambda$ of $\lambda$ over $K_0$ permutes these $n$-tuples, and such a permutation gives rise to a permutation on $(\mathbb{P}^1_K)^n$ making diagram (5.2) commute. Having fixed a labelling of the roots of $\lambda$, we see that $G_\lambda$ is canonically identified with a subgroup of $S_n$. Since $\lambda$ is separable over $K_0$, these $n!$ $n$-tuples are pairwise distinct, whence the scheme $\overline{X}$ is reduced. Also,

$$
\overline{X} \text{ is } K\text{-reducible } \iff \text{ the generic fiber of } \overline{\phi}_n \text{ is the disjoint union of non-trivial, } G_\lambda\text{-stable subsets} \\
\iff G_\lambda \text{ does not act transitively on this fiber}
$$

(5.3)

The multiplication map $(\wp^1_K)^n \to \wp^n_K$ naturally factors through every $\wp^j_K \times \wp^{n-j}_K$. That means $\overline{\phi}_n$ factors through $\phi_{n,j}$ for every $j$; therefore the diagram (5.2) factors through the diagram (5.1) for every $j$, and $\Phi_{n,j}$ is also a regular branched cover with deck transformation group isomorphic to a subgroup of $S_n$. 

Annales de l'Institut Fourier
Finally, suppose \( \lambda \) satisfies hypotheses (i)–(iii). Then \( G_\lambda = S_n \), whence the deck transformation group of \( \tilde{\phi}_n \) is also \( S_n \). By (5.3), the scheme \( X \) is reduced and \( K \)-irreducible, and so it makes sense to speak of the function field \( K(X) \). Both \( \Phi_{n,j} \) and \( \tilde{\phi}_{n,j} \) are surjective, so \( X_j^\circ \) is also \( K \)-irreducible, and so it makes sense to speak of the function field \( K(X_j^\circ) \) as well, and \( K(X)/K(P_1^1) \) is an \( S_n \)-extension of function fields. We have \( \deg \Phi_{n,j} = j!(n-j)! \), and the same argument after (5.2) shows that the deck transformation group of \( \Phi_{n,j} \) is isomorphic to a subgroup of, and hence is exactly, \( S_j \times S_{n-j} \).

**Proof of Lemma 11.** — First, recall the notations \( X_j, K_j \) etc. introduced after Lemma 9, and the fact that \( X_1 \) is given by \( \lambda = 0 \). For any \( t_0 \in P_1^1 \), the \( K \)-rational points on the fibers of \( \phi_{n,1}^\circ \) are in bijective correspondence with the \( K \)-linear factors of \( \lambda(x, t_0) \), while those on the fibers of \( \tilde{\phi}_{n,1} \) are in bijective correspondence with the \( K \)-rational points of the curve \( \lambda(x, t) = 0 \) with \( t \)-coordinates \( t_0 \). These two sets are in natural bijective correspondence with each other; the universal property of the pullback diagram (5.1) then implies that there is a \( K \)-isomorphism \( \mu_n : X_1 \to X_j^\circ \) such that \( \tilde{\phi}_{n,1} = \mu_n \phi_{n,1}^\circ \). This allows us to identify the two \( S_n \)-extensions \( K(X)/K_0 \) and \( K'/K_0 \). The \( S_j \times S_{n-j} \) subgroups in \( S_n \) are pairwise conjugate, so we can identify the intermediate subfields \( K(X_j^\circ) \) with \( K(X_j) \). That means the smooth curve \( X_j \) is the canonical desingularization of \( X_j^\circ \), and \( \tilde{\phi}_{n,j} \) is the extension of \( \phi_{n,j}^\circ \) to \( X_j \), whence the \( \text{Gal}(K'/K_0) \approx S_n \) action on the roots of \( \Lambda_j \) over \( K_0 \) is the same as that on the generic fiber of \( \phi_{n,j}^\circ \). But the points on this generic fiber are precisely the \( j \)-subsets of \( \Sigma \). \( \square \)
6. Generalized Laguerre polynomials

In this section we apply the machinery developed above to study specializations of generalized Laguerre polynomials $L_n^t(x)$ defined in the introduction. In Subsection 6.1, we study the singular locus of the plane curve $L_n$ defined by $L_n^t(x) = 0$. By analyzing the structure of maximal subgroups of $S_n$, in Subsection 6.2 we compute the genus of the intermediate subfields of $K'/K_0$ over which $\Lambda_j$ is reducible. In Subsection 6.3 we combine these ingredients to deduce Theorem 1 following the strategy outlined in Sections 2 and 5.

From now on, we fix $n$ and take $\lambda(x, t) = L_n^t(x)$, carrying over all the notation ($K_0, K_1, K', \mathcal{O}_0, G_\lambda, B_\lambda$, etc.) from Sections 2, 4, 5 to the present setting.

6.1. The singular locus of $L_n^t(x)$

Fix $n > 2$. Following Schur [29, p. 54], we homogenize $L_n^t(x)$ by setting

$$F_n(x, r, s) := (-1)^n n! s^n L_n^t(x/s)$$

$$(6.1)$$

where $k_j = j(r + js)$. Let $L_n$ be the plane curve $F_n(x, r, s) = 0$. To simplify the notation, we write $\partial_x F_j$ for $\partial F_j/\partial x$. Then we have the relations [29, p. 54]

$$(6.2) \quad x \partial_x F_m = m F_m + k_m F_{m-1}, \quad (m \geq 1, \ F_0 := 1);$$

$$(6.3) \quad F_m = (x - r - (2m - 1)s) F_{m-1} - sk_{m-1} F_{m-2}, \quad (m \geq 2).$$

Setting $s = 0$, (6.1) becomes

$$x^n - nx^{n-1} r + \frac{n(n-1)}{2} x^{n-2} r^2 - \cdots + (-1)^n r^n = (x - r)^n.$$ 

Thus $L_n$ has exactly one point along the line at infinity, namely $[1 : 1 : 0]$. Let $\iota_n : L_n \to \mathbb{P}^1_K$ be the projection map defined by $[x : r : s] \mapsto [r : s]$.

**Lemma 12.** — Suppose for some integer $j \in [0, n]$ and some point $z = [x(z) : r(z) : s(z)] \in \mathbb{P}^2_C$ with $x(z)s(z) \neq 0$, we have

$$(6.4) \quad F_{n-j}|_z = \partial_x F_{n-j}|_z = 0 \quad \text{and} \quad k_{n-j} \neq 0.$$ 

Then $F_{n-j-1}|_z = 0$ and $k_{n-j-1} \neq 0$. Moreover, if $j \leq n - 2$, then $\partial_x F_{n-j-1}|_z = 0$. 

**Annales de L’Institut Fourier**
Proof. — Since $s(z) \neq 0$, without loss of generality we can set $s(z) = 1$.

Suppose $n \geq j + 1$; when we substitute into (6.2) the first two relations in (6.4), we get $0 = k_{n-j}F_{n-j-1}|_z$, whence

\[(6.5) \quad F_{n-j-1}|_z = 0.\]

Next, suppose $k_{n-j-1} = 0$. When we use the expansion (6.1) to evaluate (6.5), we see that $x(z) = 0$, a contradiction. Finally, suppose $n \geq j + 2$. Substituting (6.5) along with the first relation in (6.4) into (6.3), we get

\[0 = -s(z)k_{n-j-1}F_{n-j-2}|_z.\]

Substitute this and (6.5) back into (6.2) and we get $x\partial_x F_{n-j-1}|_z = 0$. As $x(z) \neq 0$, that means $\partial_x F_{n-j-1}|_z = 0$. This completes the proof of the lemma. \(\square\)

Lemma 13. — For $n \geq 3$ the curve $L_n$ has no finite singular point.

Proof. — Using the relations (6.2) and (6.3), Schur [29, p. 54] showed that $F_n$, viewed as a polynomial in $x$, has discriminant

\[(6.6) \quad s^{n(n-1)/2}n!k_2k_3^2 \cdots k_{n-1}^{n-1}.\]

We are interested in the finite points on $L_n$, so for the rest of the proof we can set $s = 1$. Clearly it suffices to consider only the points on $L_n$ lying above the branch locus of $\iota_n$.

Suppose $z = (x_0, r_0)$ is a finite singular point. By (6.6) we have $r_0 \in \{-2, \ldots, -n\}$, and

\[(6.7) \quad F_n|_z = \partial_x F_n|_z = \partial_r F_n|_z = 0.\]

We claim that $x_0 \neq 0$. Suppose otherwise; set $\partial_r F_n = 0$ and then substitute $x = 0$ (recall that $s = 1$), to get

\[0 = (-1)^n \frac{\partial}{\partial r} \prod_{k=1}^{n} (r + k) = (-1)^n \sum_{m=1}^{n} \prod_{k=m+1}^{n} (r + k).\]

Set $r = r_0$ and this becomes

\[\prod_{k=1}^{n} (r_0 + k) = 0,\]

a contradiction. Thus $x_0 \neq 0$. Also, if $k_n = 0$, then from (6.1) we get $x_0 = 0$, a contradiction. Thus $k_n \neq 0$, i.e. $r_0 \neq -n$. That means the hypotheses of Lemma 12 are satisfied for $j = 0$. Applying the lemma, we find the conditions of the lemma hold for $j = 1$ as well as $r_0 \neq 1 - n$. Repeating
this procedure, we find \( r_0 \notin \{-2, \ldots, -n\} \), a contradiction. Thus \( L_n \) has no finite singular point. \( \square \)

**Lemma 14.** — Suppose \( n \geq 2 \). Then \( K(\sqrt{\text{disc } L_n^t(x)}) \) is a quadratic extension of \( K_0 \) corresponding to a smooth curve of genus \( \left[ \frac{1}{2}(n - 2) \right] \).

**Proof.** — Since \( n \geq 2 \), (6.6) says that \( \text{disc } L_n^t(x) \) is a polynomial in \( t \) whose square-free part has degree \( \left[ \frac{1}{2}n \right] \), and the lemma follows. \( \square \)

Recall that the notation of Section 4, such as \( \mathcal{O}_0, \mathcal{O}' \), etc. now applies to the case \( \lambda(x, t) = L_n^t(x) \). For \( \nu \in B_\lambda = \{-2, \ldots, -n\} \subset \mathbb{P}^1_K \), denote by \( \mathfrak{m}_\nu \) the corresponding maximal ideal in \( \mathcal{O}_0 \). Denote by \( \mathcal{O}_1 \) the coordinate ring of an affine open set of \( X_1 \) containing all places lying above every \( \nu \) with respect to the projection map \( \iota_n \). Then (6.6) says that the restriction of \( \iota_n \) to \( \mathcal{O}_0 \) is unramified outside the \( \mathfrak{m}_\nu \), and Lemma 13 says that the inclusion map \( \mathcal{O}_0 \subset \mathcal{O}' \) is an integral extension of Dedekind domains when localized at these \( \mathfrak{m}_\nu \). From (6.1), we obtain easily

\[
F_n(x, t, 1) \equiv x^{[\nu]}F_{n+\nu}(x, -t, 1) \pmod{(t - \nu)}, \quad \nu \in \{-1, -2, \ldots, -n\},
\]

which, in conjunction with (6.6), tells us that \( \mathcal{O}_1 \) has exactly one ramified maximal ideal lying above \( \mathfrak{m}_\nu \):

\[
(6.8) \quad \mathfrak{m}_\nu \mathcal{O}_1 = n_0^{[\nu]}n_1 \cdots n_s,
\]

where the \( n_i \) are pairwise distinct; in other words each branch point \( \nu \) of \( L_n^t(x) \) is simple of index \( [\nu] \). Applying Lemma 7, we deduce the following result.

**Lemma 15.** — For \( \nu \in \{-2, \ldots, -n\} \), let \( \mathcal{M}_\nu \subset \mathcal{O}' \) be a maximal ideal lying above \( \mathfrak{m}_\nu \). Then the inertia group \( I(\mathcal{M}_\nu/\mathfrak{m}_\nu) \) is generated by a cycle of length \( [\nu] \). In particular,

\[
e_\nu := e(\mathcal{M}_\nu/\mathfrak{m}_\nu) = [\nu]. \quad \square
\]

**Proposition 4.** — Suppose \( n \geq 6 \). Then the geometric genus of \( L_n \) is > 1.

**Proof.** — First, assume \( n \geq 7 \). Thanks to Lemma 15, we can apply Lemma 3 with \( V = \{-n, 1 - n, \ldots, 5 - n\} \). Since there is a unique prime in \( \mathcal{O}_1 \) above \( \mathfrak{m}_\nu \) with non-trivial ramification index \( -nu \), we have
\[ c_1(\nu) = n + \nu, \] and (4.1) becomes
\[ \frac{1}{2} \sum_{i=0}^{5} \left( 1 - \frac{1}{d(n-i)} \right) \]
\[ - \frac{1}{2} \sum_{i=0}^{5} \left( 1 - \frac{1}{d(n-i)} \right) i. \]

For any six consecutive, positive integers, exactly two of them are prime to 6, another one is odd, and the remaining three are even. Thus the first \( i \)-sum in (6.9) is
\[ \geq -2 + 6 - 2 \times \frac{1}{5} - \frac{1}{3} - 3 \times \frac{1}{2} = \frac{53}{30}. \]

Thus (6.9) yields
\[ g(\mathcal{L}_n) \geq 1 + \frac{53n}{60} - \frac{1}{2} \left( 1 - \frac{1}{n} \right) (0 + 1 + 2 + 3 + 4 + 5), \]
which is \( > 1 \) if \( n > 10 \). Using the more refined version (6.9) we find that in fact \( g(\mathcal{L}_n) > 1 \) if \( n \geq 7 \). Using the full Riemann-Hurwitz formula, or the \textsc{algcurves} package in \textsc{maple}, we find that \( g(\mathcal{L}_6) = 4 \). This completes the proof of the proposition. \( \square \)

Remark 7. — By analyzing the singularity at infinity, one in fact has a nice formula \( g(\mathcal{L}_n) = [(-1 + \frac{1}{2} n)^2] \) valid for all \( n \).

6.2. Genus of maximal subgroups

In this subsection, we carry out the calculations which will be necessary ingredients for the application of Theorem 3 to \( \mathcal{L}_n(x) \) in the next section. This involves a mixed strategy in the following sense. For \( n \geq 10 \), we show that every minimal intermediate subfield \( E \) of \( K'/K_0 \) has genus \( > 1 \), thanks to Lemma 14 and Proposition 5(a) below. It then follows from Riemann-Hurwitz that every proper intermediate subfield has genus \( > 1 \). For \( 6 \leq n \leq 9 \), the quadratic extension inside \( K'/K_0 \) has genus 0 or 1, but we have shown in Proposition 3 that \( \Lambda_j \) is not reducible over this field. It remains, then, to check for \( 6 \leq n \leq 9 \) that proper subgroups of \( A_n \) give fixed fields of genus \( > 1 \), and this is the content of Proposition 5(b). We treat \( n = 5 \) “by hand.”

Proposition 5. — (a) Suppose \( n \geq 6 \). If \( E \) is a maximal subgroup of \( G_\lambda \) other than \( A_n \), with corresponding fixed field \( E \), then \( g(X_E) > 1 \).
(b) Suppose $6 \leq n \leq 9$. If $E$ is a proper maximal subgroup of $A_n \subset G_\lambda$, with corresponding fixed field $E$, then $g(X_E) > 1$.

Proof. — We begin with (a). Up to conjugation, the maximal subgroups of $S_n$ other than $A_n$ belong to exactly one of the following three types [8, p. 268]:

- imprimitive subgroups: the wreath products $S_j \wr S_{n/j}$ in its imprimitive action\(^{(2)}\), for some divisor $j$ of $n$, $1 < j < n$;
- intransitive subgroups: $S_{n,j}$ for some $1 \leq j < \frac{1}{2}n$ (note that if $n$ is even then $S_{n,n/2}$ is contained in $S_{n/2} \wr S_2$);
- a primitive subgroup of $S_n$.

For each of the three types of $E$, we use group-theoretic properties of $E$ plus ramification data of $K'/K_0$ to bound (4.1) from below for large $n$, and then handle the remaining cases individually. Note that among any four consecutive integers $\geq 2$, exactly one of them is prime to 6, another one is odd, and the other two are even. Recall the notation $d(e)$ from Definition 1 and we see that for $n \geq 6$,

$$\begin{align*}
-2 + \sum_{j=0}^{3} \left(1 - \frac{1}{d(n-j)}\right) &\geq -2 + 4 - \frac{1}{2} - \frac{1}{2} - \frac{1}{3} - \frac{1}{5} = \frac{7}{15}.
\end{align*}$$

We will also make repeated use of the following remark. For the rest of this proof, we will take

$$V = \{3-n, 2-n, 1-n, -n\}.$$ 

By Lemma 15, the inertia group of any $\nu \in V$ is generated by a single cycle, which will allow us to use Lemma 6 in conjunction with (4.1).

We now consider each of the different types of maximal subgroups in turn.

- **Case: imprimitive subgroups** $S_j \wr S_{n/j}$. — First, suppose $n \geq 7$. Since $n-3 > \frac{1}{2}n$, $S_j \wr S_{n/j}$ does not contain any $(n-s)$-cycle for $0 \leq s \leq 3$. That means $c_1(\nu) = 0$ for every $\nu \in V$. Recall (6.11) and (4.1) becomes

$$g(X_E) \geq 1 + \frac{7}{30}[S_n : S_j \wr S_{n/j}] > 1.$$ 

Next, suppose $n = 6$. The same reasoning as above shows that $c_1(\nu) = 0$ if $\nu \leq 2-n$, and if $j = 2$, then $c_1(3-n) = 0$ as well. So as before $g(X_E) > 1$ if $E \simeq S_2 \wr S_3$. It remains to consider the case $E \simeq S_3 \wr S_2 \simeq (S_3 \times S_3) \times \mathbb{Z}/2$. A representative of the non-trivial coset of $S_3 \times S_3$ in $(S_3 \times S_3) \times \mathbb{Z}/2$ (as a subgroup of $S_6$) is $(14)(25)(36)$; from this we check that elements

\(^{(2)}\) i.e. the stabilizer of a partition of $n$ letters into $n/j$ disjoint subsets of equal size.
in this non-trivial coset all have even order. Thus the order 3 elements in \((S_3 \times S_3) \times \mathbb{Z}/2\) are all contained in \(S_3 \times S_3\). The latter has a unique Sylow 3-subgroup, namely \(\mathbb{Z}/3 \times \mathbb{Z}/3\), so \(\mathcal{E}\) has four distinct \(\mathbb{Z}/3\)-subgroups, whence (4.7) gives \(c_1(-3) = \frac{8}{\#S_3 \times S_3} \cdot 3! = 2\). Thus

\[
g(X_E) \geq 1 + \frac{6!/72}{2} \cdot \frac{7}{15} - \frac{1}{2} \cdot 2 \cdot \left(1 - \frac{1}{3}\right) > 1,
\]
as desired.

- **Case: intransitive subgroups** \(S_{n,j}\) with \(1 \leq j < \frac{1}{2}n\). — For \(j > 3\), \(S_{n,j}\) contains no cycle of length \(\geq n - 3\), so \(c_1(\nu) = 0\) for every \(\nu \in V\). Thus (4.1) gives \(g(X_E) > 1\).

Next, suppose \(j = 3\), so that we can take \(n \geq 7\). Then \(c_1(\nu) = 0\) for \(|\nu| > n - 3\), and (4.8) gives \(c_1(3-n) < 6(n-3)\). Thus (4.1) becomes

\[
g(X_E) \geq 1 + \frac{7}{30} \cdot \frac{n!}{3!(n-3)!} - \frac{6n - 19}{2} \left(1 - \frac{1}{d(n-3)}\right),
\]
which is easily seen to be \(> 1\) for \(n \geq 7\) (for \(n \geq 8\), use the trivial bound 
\(d(n-3) \leq n - 3\)).

Now, take \(j = 2\). Since \(n \geq 6\), the only cycles of order \(n - 2\) and \(n - 3\) in \(S_{n,2} = S_2 \times S_{n-2}\) come from the cycles in \(S_{n-2}\) of such order. There are \((n-3)!\) and \((n-2)(n-4)!\) of them, respectively, so by (4.7),

\[
c_1(n-2) = 1\quad\text{and}\quad c_1(n-3) = 3,
\]
whence (4.1) plus (6.11) gives

\[
g(X_E) \geq 1 + \frac{7}{30} \cdot \frac{n(n-1)}{2} - \frac{1}{2} \left(1 - \frac{1}{d(n-2)}\right) - \frac{3}{2} \left(1 - \frac{1}{d(n-3)}\right).
\]
This is \(> 1\) for \(n \geq 5\), so we are done.

Finally, consider the case \(j = 1\). Then \(X_E\) is simply the curve \(X_1\), which we saw right before the statement of Lemma 10 is simply the curve \(\mathcal{L}_n\) defined by \(L_n^{(1)}(x)\). By Proposition 4, this curve has geometric genus \(> 1\) if \(n \geq 6\), so we are done.

- **Case: primitive subgroups.** — Let \(\mathcal{E} \subset S_n\) be a primitive subgroup other than \(A_n\). By Bochert’s theorem [8, p. 79],

\[
[S_n : \mathcal{E}] \geq \left[\frac{n+1}{2}\right]!
\]
Using (4.8) together with the trivial estimate $1 - 1/d(e_\nu) \leq 1 - 1/n$, (4.1) becomes

\[ g(X_E) \geq 1 + \frac{7}{30} [S_n : \mathcal{E}] - \frac{1}{2} \left(1 - \frac{1}{n}\right) ((n - 1) + (n - 2) + (2n - 5)) + (6n - 19) \]

(6.12)

\[ g(X_E) \geq 1 + \frac{7}{30} \left[\frac{n + 1}{2}\right]! - \left(1 - \frac{1}{n}\right) \frac{10n - 27}{2} \]

(6.13)

\[ g(X_E) \geq 1 + \frac{7\sqrt{n \pi n}}{30} \left(\frac{n}{2e}\right)^{n/2} - \left(1 - \frac{1}{n}\right) \frac{10n - 27}{2} \]

Stirling formula [1, p. 24].

From (6.13) we get that $g(X_E) > 1$ if $n \geq 15$. Using the sharper form (6.12), we see that in fact $g(X_E) > 1$ if $n \geq 11$. For $n = 9, 10$, if we use the original inequality (4.1), we also obtain $g(X_E) > 1$. To handle the remaining values of $n$, i.e. 6, 7, 8, we make use of classification of primitive groups of small degree [2].

\( \triangleright n = 8. \) — $S_8$ has two maximal primitive subgroups other than $A_7$, namely $\text{PGL}(2, \mathbb{F}_7)$ and $2^3 \cdot \text{PSL}_2(\mathbb{F}_7)$ (a group with normal subgroup $(\mathbb{Z}/2)^3$ and with quotient $\text{PSL}_2(\mathbb{F}_7)$). In particular, both groups contain no element of order 5, so the $c_1$-term in (4.1) corresponding to the branched point $\nu = -5$ is zero. For the group $\text{PGL}_2(\mathbb{F}_7)$, (4.1) then becomes

\[ 1 + \frac{7}{30} \frac{8!}{336} - \frac{1}{2} \left(7 \left(1 - \frac{1}{2}\right) + 6 \left(1 - \frac{1}{7}\right) + 11 \left(1 - \frac{1}{2}\right)\right) > 1. \]

To handle the group $2^3 \cdot \text{PSL}_2(\mathbb{F}_7)$ we need to refine our estimate for the $c_1(-7)$-term. Sylow theory dictates that $2^3 \cdot \text{PSL}_2(\mathbb{F}_7)$ has at most 64 Sylow 7-subgroups, all of order 7, so $2^3 \cdot \text{PSL}_2(\mathbb{F}_7)$ has at most $64 \times 6 = 384$ elements of order 7. Substitute this into (4.7) and we find that $c_1(-7) \leq 2$, whence (4.1) becomes

\[ 1 + \frac{7}{30} \frac{8!}{336} - \frac{1}{2} \left(7 \left(1 - \frac{1}{2}\right) + 2 \left(1 - \frac{1}{7}\right) + 11 \left(1 - \frac{1}{2}\right)\right) > 1. \]

\( \triangleright n = 7. \) — $S_7$ has a unique maximal primitive subgroup other than $A_7$, namely $\text{PSL}_2(\mathbb{F}_7)$. It has 42 elements of order 4, no element of order 5, and 48 elements of order 7, so $c_1(-4) = \frac{42}{168} \cdot 6 = 6$, $c_1(-5) = 0$, and $c_1(-7) = \frac{48}{168} \cdot 7 = 2$, whence (4.1) becomes

\[ g(X_E) \geq 1 + \frac{7}{30} \frac{7!}{168} - \frac{1}{2} \left(2(1 - \frac{1}{7}) + 5 \left(1 - \frac{1}{2}\right) + 6 \left(1 - \frac{1}{2}\right)\right) > 1. \]

\( \triangleright n = 6. \) — $S_6$ has a unique maximal primitive subgroup other than $A_6$, namely $\text{PGL}_2(\mathbb{F}_5) \simeq S_5 \simeq S_{6,1}$. For such intransitive groups we already...
saw that \( g(X_E) > 1 \), so we are done for \( n = 6 \). This completes the proof of (a).

Let us now turn to (b). We will make extensive use of the Atlas [3] to determine the maximal subgroups of these \( A_n \), as well as the number of conjugacy classes of elements in \( A_n \) and \( \text{PSL}_2(\mathbb{F}_q) \). Recall that \( V = \{-n, 1-n, 2-n, 3-n\} \).

\( \triangledown n = 9. \) — According to the Atlas, the maximal subgroups\(^{(3)} \) of \( A_9 \) are \( A_8, S_7 \), plus others of indices \( \geq 84 \) in \( A_9 \). First, consider those \( E \) of index \( \geq 84 \) in \( A_9 \). Then \( [S_9 : E] \geq 168 \), and (4.1) becomes

\[
g(X_E) \geq 1 + \frac{7}{30} 168 - \frac{1}{2} \left( (1 - \frac{1}{3}) c_1(-9) + \left( 1 - \frac{1}{2} \right) c_1(-8) \right) + \left( 1 - \frac{1}{7} \right) c_1(-7) + \left( 1 - \frac{1}{2} \right) c_1(-6) \geq 1 + \frac{196}{5} - \frac{1}{2} \left( \frac{2}{3} 8 + \frac{1}{2} 7 + \frac{6}{7} 13 + \frac{1}{2} 35 \right) > 1,
\]

which is satisfactory. Next, take \( E = A_8 \). Then \( [S_9 : E] = 18 \), and \( A_8 \) has no cycles of order 9, 8 or 6, so \( c_1(-9) = c_1(-8) = c_1(-6) = 0 \). There are \( 8!/7 \) elements of order 7 in \( A_8 \), so \( c_1(-7) = \frac{8!/7}{2} 7 \cdot 2 = 4 \). Thus

\[
g(X_E) \geq 1 + \frac{7 \cdot 18}{30} - \frac{4}{2} \left( 1 - \frac{1}{7} \right) > 1.
\]

Finally, take \( E = S_7 \). Then \( [S_9 : E] = 72 \) and \( S_7 \) has no element of order 9 or 8, so

\[
g(X_E) \geq 1 + \frac{7 \cdot 72}{30} - \frac{1}{2} \left( (1 - \frac{1}{7}) 13 + \left( 1 - \frac{1}{2} \right) 35 \right) > 1.
\]

This completes the case \( n = 9 \).

\( \triangledown n = 8. \) — The maximal subgroups of \( A_8 \), along with their indices in \( A_8 \), are

\[
(A_7, 8); \ (2^3 : \text{PSL}_2(\mathbb{F}_7), 15); \ (S_6, 28);
\]
\[
(2^4 : (S_3 \times S_3), 35); \ ((A_5 \times 3) : 2, 56).
\]

From (4.8) we get the standard estimates

\[
(6.14) \quad c_1(-8) < 8, \quad c_1(-7) < 7, \quad c_1(-6) < 6 \cdot 2!.
\]

The case \( E = 2^3 : \text{PSL}_2(\mathbb{F}_7) \) has already been dealt with in the course of proving Proposition 5. For \( E = 2^4 : (S_3 \times S_3) \), it has no element of order 5

---

\(^{(3)} \) In what follows we will consider the isomorphism classes, and not conjugacy classes, of maximal subgroups of these \( A_n \). For the purpose of computing \( g(X_E) \) this is sufficient.
or 7, whence $c_1(-5) = c_1(-7) = 0$. We have $[S_n : \mathcal{E}] = 70$, so (4.1) becomes

$$g(X_E) \geq 1 + \frac{7}{30} \cdot 70 - \frac{1}{2} \left( (1 - \frac{1}{2})^5 + (1 - \frac{1}{2}) \cdot 23 \right) > 1.$$  

Next, take $\mathcal{E} = (A_5 \times 3) : 2$, i.e. a split extension with kernel $A_5 \times \mathbb{Z}/3$ and quotient $\mathbb{Z}/2$. The order 5 elements in $\mathcal{E}$ are all in $A_5 \times \mathbb{Z}/3$, and hence there are 4! of them. Thus (4.7) gives $c_1(-5) = \frac{4!}{300} \cdot 5 \cdot 3! = 2$. Also, $\mathcal{E}$ has no element of order 7, so $c_1(-7) = 0$. Thus (4.8) becomes

$$g(X_E) \geq 1 + \frac{7}{30} \cdot 112 - \frac{1}{2} \left( (1 - \frac{1}{2})^8 + (1 - \frac{1}{2}) \cdot 6 + (1 - \frac{1}{5}) \cdot 2 \right) > 1.$$  

For $\mathcal{E} = S_6$, again it has no order 7 elements so $c_1(-7) = 0$. It has $6!/5$ order 5 elements, so $c_1(-5) = \frac{6!/5}{6} \cdot 5 \cdot 3! = 6$. Thus (4.1) becomes

$$1 + \frac{7}{30} \cdot 56 - \frac{1}{2} \left( (1 - \frac{1}{2})^8 + (1 - \frac{1}{2}) \cdot 6 + (1 - \frac{1}{5}) \cdot 6 \right) > 1.$$  

Now take $\mathcal{E} = A_7$. There are no cycles of length 6 or 8 in $A_7$, so $c_1(-8) = c_1(-6) = 0$. There are 6! order 7 elements and $7!/(5 \cdot 2!) = 7$ order 5 elements in $A_7$, so $c_1(-7) = c_1(-5) = 1$. Thus

$$g(X_E) \geq 1 + \frac{7}{30} \cdot 8 - \frac{1}{2} \left( (1 - \frac{1}{7}) + (1 - \frac{1}{5}) \right) > 1.$$  

$n = 7$. — The maximal subgroups of $A_7$, along with their indices in $A_7$, are

$$(A_6, 7); \ (\text{PSL}_2(\mathbb{F}_7), 15); \ (S_5, 21); \ ((A_4 \times 3) : 2, 35).$$  

Note that (4.8) gives the following estimates

$c_1(-7) < 7, c_1(-6) < 6, c_1(-5) < 5 \cdot 2, c_1(-4) < 4 \cdot 6.$  

First, take $\mathcal{E} = (A_4 \times 3) : 2$. Then $\mathcal{E}$ has no element of order 7 or 5, so $c_1(-7) = c_1(-5) = 0$. Thus (4.1) becomes

$$g(X_E) \geq 1 + \frac{7}{30} \cdot 70 - \frac{1}{2} \left( (1 - \frac{1}{2})^5 + (1 - \frac{1}{2}) \cdot 23 \right) > 1.$$  

Next, take $\mathcal{E} = S_5 \subset A_7$. Then it has no cycles of order 7 or 6, so $c_1(-7) = c_1(-6) = 0$. It has 4! elements of order 5, and 5!/4 elements of order 4. Thus $c_1(-5) = 2$ and $c_1(-4) = 6$. Thus

$$g(X_E) \geq 1 + \frac{7}{30} \cdot 42 - \frac{1}{2} \left( (1 - \frac{1}{5})^2 + (1 - \frac{1}{2}) \cdot 6 \right) > 1.$$  

Now, take $\mathcal{E} = A_6 \subset A_7$. It has no order 7 elements and no cycles of order 6 or 4. It has $6!/5$ order 5 elements, so $c_1(-5) = 2$. Thus

$$g(X_E) \geq 1 + \frac{7}{30} \cdot 14 - \frac{1}{2} \left( 1 - \frac{1}{5} \right)^2 > 1.$$  

Finally, take $\mathcal{E} = \text{PSL}_2(\mathbb{F}_7)$. It has 42 elements of order 4, none of order 5.
or 6, and 48 elements of order 7. Thus \( c_1(-4) = \frac{42}{105} \cdot 4 \cdot 3! = 6, c_1(-5) = c_1(-6) = 0, c_1(-7) = \frac{48}{105} \cdot 7 = 2. \) Then
\[
\begin{align*}
g(X_E) &> 1 + \frac{7}{30} \cdot 30 - \frac{1}{2} \left( \left( 1 - \frac{1}{7} \right) 2 + \left( 1 - \frac{1}{2} \right) 6 \right) > 1. \\
\end{align*}
\]

\( \triangleright n = 6. \) — The maximal subgroups of \( A_6, \) along with their indices in \( A_6, \) are
\[
(A_5, 6); \quad ((\mathbb{Z}/3 \times \mathbb{Z}/3) \rtimes \mathbb{Z}/4, 10); \quad (S_4, 15).
\]

First, take \( E = S_4. \) It has six elements of order 4, eight of order 3, and none of order 5 or 6. Thus \( c_1(-4) = 2, c_1(-3) = 6, c_1(-6) = c_1(-5) = 0, \) whence \( g(X_E) > 1. \)

Next, take \( E = A_5. \) It has twenty-four elements of order 5, twenty elements of order 3, and none of order 6 or 4. Thus \( c_1(-5) = 1, c_1(-3) = 3, c_1(-6) = c_1(-4) = 0, \) whence \( g(X_E) > 1. \)

Finally, take \( E = (\mathbb{Z}/3 \times \mathbb{Z}/3) \rtimes \mathbb{Z}/4. \) Then \( c_1(-5) = 0. \) There are 8 elements of order 3, and hence \( \leq 27 \) elements of order 4. Thus \( c_1(-3) = 4 \) and \( c_1(-4) \leq 6. \) It follows that \( g(X_E) > 1. \) This completes the proof of (b). \( \square \)

### 6.3. Proof of Theorem 1

**Step I.** — First, we treat the case \( n = 5 \) using an argument specific to quintics. A separable quintic over \( K \) (not necessarily irreducible) has a solvable Galois group if and only if its resolvent sextic has a root in \( K \) [9]. Compute the resolvent sextic of \( L_5^{(i)}(x) \) using the formula in [9] and set it equal to \( (x - 10A)(x^5 + c_1x^4 + \cdots + c_5), \) obtaining six equations in \( t, A, c_1, \ldots, c_5. \) Eliminate \( c_1, \ldots, c_5 \) from the six equations using MAPLE and we arrive at a single equation in \( t \) and \( A: \)

\[
\begin{align*}
A^6 + (12t^2 - 24t)A^5 + (120t^2 + 60t^3)A^4 & \\
+ (720t^3 + 2120t^4 + 1600t^5 + 360t^6)A^3 & \\
+ (-5040t^4 - 11580t^6 - 4200t^7 - 540t^8 - 13200t^5)A^2 & \\
+ (10368t^4 + 39744t^5 + 48864t^6 + 14448t^7 - 12480t^8 & \\
- 9360t^9 - 1728t^{10})A & \\
- 3(5832t^5 + 26892t^6 + 50814t^7 + 50645t^8 + 28406t^9 + 8735t^{10} & \\
+ 1278t^{11} + 54t^{12}). & \\
\end{align*}
\]

Using the \texttt{ALGCURVES} package in MAPLE, we find that this equation is absolutely irreducible and defines a plane curve with geometric genus 3.
Thanks to Faltings, that means $L_5^{(\alpha)}(x)$ is $K$-irreducible and is not solvable for $\alpha \in \text{af} \ K$. This completes the proof for the case $n = 5$. From now on, assume that $n \geq 6$.

**Step II.** — Given a number field $K$, we claim that if there exists one $\beta \in K$ for which $L_n^{(\beta)}(x)$ has $S_n$-Galois group over $K_0$, then Theorem 1 holds for this $K$.

By (6.6), the discriminant of $L_n^{(t)}(x)$ is not constant. Since $n \geq 5$, Lemma 8 applies so that the existence of this one $\beta$ yields the necessary hypotheses on $K'/K_0$. For $n \geq 10$, the genus of the fixed field of every proper maximal subgroup of $G_\lambda$ is greater than 1 (Proposition 5(a) and Lemma 14). By Riemann-Hurwitz, since $K$ has characteristic 0, $g(X_E) \leq g(X_{E'})$ whenever $E \subseteq E'$. Thus, for $n \geq 10$, every non-trivial intermediate subfield of $K'/K_0$ has genus greater than 1. For degrees $n = 6, 7, 8, 9$, we have shown, (a) that proper maximal subgroups of $A_n$ and $S_n$ have genus greater than one (Proposition 5), and (b) over the quadratic subfield of $K_0$ in $K'$, the polynomials $\Lambda_j$ are all irreducible (Proposition 3). Thus, for all $n \geq 6$, the hypotheses of Theorem 3 are satisfied.

We therefore obtain the first part of Theorem 1(a) for $n \geq 7$. By Lemma 14, if $n \geq 10$ (resp. $n \geq 6$) then the set of $t \in K$ corresponding to even Galois groups are parameterized by a curve of geometric genus $\geq 2$ (resp. $\geq 1$). The rest of Theorem 1 for $n \geq 7$ now follows.

For $n = 6$, the argument for Theorem 3 only shows that the degree of the splitting field of all but finitely many $L_n^{(\alpha)}(x)$ over $K$ is divisible by $\text{LCM}(\binom{6}{2}, \binom{6}{3}) = 60$. To improve this we use a different test function. By Lemma 8(a), the fixed field of $K'/K_0$ by $S_3 \times \{1\} \subset S_{6,3}$ corresponds to a smooth projective curve $X_{3,0}$ plus a $K$-morphism $\xi_{3,0} : X_{3,0} \to \mathbb{P}^1_K$. Write $\Lambda_{3,0}(x, t) = 0$ for the corresponding birational plane curve. The same argument as in Lemma 11 shows that the roots of $\Lambda_{3,0}(t)$ over $K_0$ are in bijective correspondence with triples of roots of $L_6^{(t)}(x)$ over $K_0$. Argue as in Proposition 3 and we see that $\Lambda_{3,0}(x, t)$ is irreducible over the fixed field of $K'/K_0$ by $A_6$. The discussion in Subsection 6.2 is now applicable, and we see that for $\alpha \in \text{af} \ K$, the degree of the splitting field of $L_n^{(\alpha)}(x)$ over $K$ is divisible by $\deg \xi_{3,0} = |S_6 : S_3 \times \{1\}| = 120$. By the classification of transitive subgroups of $S_6$ [8, p. 60], we are done.

**Step III.** — Schur [28] showed that $L_n^{(0)}(x)$ is $\mathbb{Q}$-irreducible and has $S_n$ Galois group. That means $L_n^{(0)}(x) = 0$ has $S_n$ Galois group over $\mathbb{Q}(t)$. Apply Step II and we get Theorem 1 for $K = \mathbb{Q}$. In particular, $\lambda(x, \alpha)$ has $S_n$ Galois group over $\mathbb{Q}$ for all but finitely many $\alpha \in \mathbb{Z}$. From (6.6)
we see that, for any finite set of primes \( \Sigma \), infinitely many of these \( S_n \)-extensions of \( \mathbb{Q} \) must be ramified outside \( \Sigma \). There are only finitely many number fields of bounded degree which are unramified outside \( \Sigma \), so for any fixed number field \( K \), there exist infinitely many \( \alpha' \in \mathbb{Q} \) so that any root of \( L_n(\alpha')(x) \) defines a degree \( n \) extension \( L_{\alpha'}/\mathbb{Q} \) with \( S_n \)-Galois closure and is ramified at a prime which is unramified in \( K/\mathbb{Q} \). Since \( S_n \) has no subgroup of index \( < n \), that means \( L_{\alpha'} \cap K = \mathbb{Q} \), whence \( L_n(\alpha')(x) \) also has \( S_n \) Galois group over \( K \). Apply Step II with \( \beta = \alpha' \) and we are done. \( \square \)

7. Simple covers

Let \( Y \) be a smooth projective curve defined over a number field \( K \), and let \( \pi : Y \to \mathbb{P}^1_K \) be a \( K \)-morphism of degree \( n \). We say that \( \pi \) is a simple cover if the fiber above every point in \( \mathbb{P}^1_K \) contains at least \( n - 1 \) distinct points. By [14, top of p. 549], the (geometric) Galois group of a simple \( n \)-cover is precisely \( S_n \). Say \( Y \) has genus \( g \); then the Riemann-Hurwitz formula implies that the number of branch points of \( \pi \) is exactly

\[
\#B_\pi = 2g + 2n - 2.
\]

Over an algebraically closed field, if \( n \geq g + 1 \) then every smooth projective curve of genus \( g \) admits a simple cover of degree \( n \) [14, Prop. 8.1].

Suppose \( \lambda(x, t) \in K[x, t] \) is irreducible over \( K_0 = K(t) \) of degree \( n \) and defines a simple cover \( K_1/K_0 \) (in the notation of Section 2). To simplify the exposition, suppose \( K \) is algebraically closed in the splitting field \( K' \) of \( \lambda \) over \( K_0 \). The following example of Müller shows that we cannot expect all but finitely \( K \)-specializations of \( \lambda \) to be \( K \)-irreducible, let alone having the same Galois group as \( \lambda \). Consider the transpositions \( g_1 = (1, 2), g_2 = (2, 3), \ldots, g_{n-2} = (n-2, n-1), g_{n-1} = (n-1, n), g_n = (n-1, n), g_{n+1} = (n-2, n-1), \ldots, g_{2n-3} = (2, 3), g_{2n-2} = (1, 2) \). Note that the product of these \( g_i \) is 1, and that they generate \( S_n \). So by the Riemann existence theorem [34, Cor. 7.3], there exists a degree \( n \) branched cover \( X_n \to \mathbb{P}^1_K \) with exactly \( 2(n-1) \) branched points over \( K \), such that the inertia group of the \( i \)-th branch point is generated by \( g_i \). By Riemann-Hurwitz, the cover with this description has geometric genus zero and is a simple cover. So taking a finite extension \( L/K \) if necessary, there are infinitely many \( L \)-rational specializations of this cover with an \( L \)-linear factor.

This example shows that an analogue of Theorem 1 applicable to all simple covers of sufficiently large degree does not exist. But if we start with a simple cover of genus at least 2, then we can prove an analogue of
Theorem 1, as in Part (b) of Theorem 4 below. Moreover, even if we start with a simple cover of genus \( \leq 1 \), Part (a) below says that all but finitely many specializations are either irreducible or factor as a linear times a degree \( n - 1 \) irreducible factor. Müller kindly sent us a proof of (a) and (b) of Theorem 4 based on a deep result of Liebeck and Saxl [23] (which uses the classification of finite simple groups). The proof we give here is a variant of Müller’s in which we can avoid using [23] by relying on the interpretation of the curve \( X_j \) introduced in Section 5 as the variety whose \( K \)-rational points parametrize the \( K \)-rational degree \( j \) factors of \( \lambda \).

**Theorem 4.** — Let \( \lambda(x, t) \) be an irreducible polynomial over \( K(t) \) defining a simple cover \( \pi : Y \to \mathbb{P}^1_K \) of degree \( n \geq 5 \) and geometric genus \( g = g_Y \geq 0 \). If \( g = 0 \), assume \( n \geq 6 \). Then,

(a) For \( \alpha \in K \), the specialization \( \lambda(x, \alpha) \) has a \( K \)-irreducible factor of degree \( \geq n - 1 \).

(b) If \( g_Y \geq 2 \), then for \( \alpha \in K \), the specialization \( \lambda(x, \alpha) \) is \( K \)-irreducible.

(c) If \( g_Y \geq 2 \) and \( n \geq 7 \), for \( \alpha \in K \), the Galois group of \( \lambda(x, \alpha) \) over \( K \) is \( S_n \).

**Proof.** — We first set up some notation and make a preliminary calculation. Suppose \( E \) is a maximal subgroup of \( S_n \). Recall that \( K'/K_0 \) is the Galois closure of the function field extension \( K_1/K_0 \) defined by the simple cover \( \pi \). This yields an action of \( \text{Gal}(K'/K_0) \cong S_n \) on the generic fiber of \( \pi_E \). By Galois theory, this action, call it \( \rho_E \), is simply the left-action of \( S_n \) on the left cosets of \( E \) in \( S_n \); it is the natural degree \( n \) action of \( S_n \) if only if \( E \) is conjugate to \( S_n \). Let \( \mu(E) \) be the largest integer \( m \) such that, under the \( \rho_E \)-action, every transposition of \( S_n \) moves at least \( m \) points. Since \( \pi_E \) is a quotient of the Galois closure of the simple cover \( \pi \), the ramification index of \( \pi_E \) at any maximal ideal \( n \) of an affine coordinate ring of \( X_E \) divides 2 (Lemma 7). By definition of \( \mu(E) \), there are \( \mu(E)/2 \) \( \mathcal{O}_E \)-primes \( n \) above \( m \) with \( e(n/m) = 2 \), thus for any \( m \in B_\pi \), as \( n \) runs through all maximal ideals of \( \mathcal{O}_E \) lying above \( m \), we have

\[
\sum_{n/m} (e(n/m) - 1) f(n/m) \geq \mu(E)/2.
\]

By Lemma 8 (b), the branch locus of \( \pi_E \) is exactly \( B_\pi \). Thus Riemann-Hurwitz gives

\[
2(N_E - 1 + g_E) \geq \#B_\pi \times \mu(E)/2.
\]

We now proceed to prove (a) and (b) together. Fix \( j \in [1, \frac{1}{2} n] \) and recall from Section 5.1 that \( X_j \) is the curve cut out by \( S_{n,j} = S_j \times S_{n-j} \subset G_\lambda \).
Suppose \( \lambda(x, \alpha) \) has a \( K \)-rational degree \( j \) factor for infinitely many \( \alpha \in K \). Then Proposition 2 implies that \( g(X_j) \leq 1 \). But the function field of \( X_j \) is the fixed field \( E = K_j \) of \( \mathcal{E} = S_{n,j} \), so by Lemma 11 (recall the notation introduced at the beginning of Subsection 5.2), \( \rho_E \) is the action of \( G_\lambda \) on the set of \( j \)-subsets of \( \Sigma = \{\lambda_1, \ldots, \lambda_n\} \). Thus, \( N_E = \binom{n}{j} \), and \( \mu(\mathcal{E}) = 2\binom{n-2}{j-1} \). Since \( g_E = g_{X_j} \leq 1 \), combining (7.2) with (7.1) gives

\[
(7.3) \quad \mu(\mathcal{E}) \leq 2N_E/(n + g_Y - 1) \leq 2N_E/(n - 1).
\]

Thus, we have

\[
(7.4) \quad 2\binom{n-2}{j-1} \leq \frac{2}{n + g_Y - 1} \binom{n}{j}.
\]

This inequality simplifies to \( j(n - j) \leq n(n - 1)/(n + g - 1) \). Since \( n \geq 5 \), this is only possible if \( g_Y \leq 1 \) and \( j = 1 \). We have therefore proved (a) and (b). To prove (c), assuming now that \( g_Y \geq 2 \), and \( n \geq 7 \), we have already seen that the fixed field of the intransitive maximal subgroups \( S_{n,j} \) have genus at least 2. Now we consider a transitive maximal subgroup \( \mathcal{E} \) of \( G_\lambda \). First suppose \( \mathcal{E} \) is primitive. By a theorem of Jordan (see e.g. [35, p. 39]), a primitive subgroup of \( S_n \) containing an element of prime order \( p \leq n - 3 \) contains \( A_n \). Assuming only \( n \geq 5 \), therefore, if our primitive subgroup \( \mathcal{E} \) contains a 2-cycle, then \( \mathcal{E} \) is \( S_n \). Thus, we may assume \( \mathcal{E} \) has no transpositions. Recalling that \( \#B_\pi = 2g + 2n - 2 \), (4.1) and (4.7) combine to give \( g(X_\mathcal{E}) > 1 \) in this case. It remains only to consider a maximal subgroup \( \mathcal{E} \) which is transitive but not primitive, i.e. \( \mathcal{E} = S_j \wr S_k \) where \( n = jk \) is a non-trivial factorization of \( n \). For such an \( \mathcal{E} \), and an arbitrary branch point \( \nu \in B_\pi \), we have

\[
c_1(\nu) = \frac{j(k-1)k/2}{\#\mathcal{E}} \cdot 2 \cdot (jk - 2)!,
\]

giving us the estimate

\[
g(X_\mathcal{E}) \geq 1 + \frac{(jk)!}{2\#\mathcal{E}} \left(-2 + \frac{\#B_\pi}{2}\right) - \frac{\#B_\pi \cdot j(j-1)k}{4\#\mathcal{E}}(jk - 2)!
\]
\[
\geq 1 + \frac{1}{4} \frac{jk(jk - 2)!}{\#\mathcal{E}} \left(\#B_\pi j(k - 1) - 4jk + 4\right)
\]
\[
\geq 1 + \frac{1}{4} \frac{jk(jk - 2)!}{\#\mathcal{E}} \left(jk \left(\frac{\#B_\pi}{2} - 4\right) + 4\right) \quad \text{since } k \geq 2.
\]

For \( n \geq 5 \), we have \( \#B_\pi = 2g + 2n - 2 \geq 8 \), hence the right hand side of the last expression above is greater than 1.
We have shown that for all minimal subfields $E$ of $K'/K_0$, $g(E) > 1$, hence the same is true for all its subfields by Riemann-Hurwitz. Now we can apply Theorem 3 to conclude the proof. \hfill \Box

Remark 8. — The argument above plus Theorem 3 shows that if $g_Y \geq 2$ then the Galois group of $\lambda(x, \alpha)$ has order divisible by 60 (if $n = 6$) and by 20 (if $n = 5$) for $\alpha \in \text{af} K$. We do not know if the Galois groups are in fact $S_6$ and $S_5$, respectively, for $\alpha \in \text{af} K$.

Acknowledgments. — We are grateful to P. Müller for pointing out an error in the last section of an earlier draft, and for sending us a number of helpful remarks, including his proof of Theorem 4. We would like to thank B. Edixhoven for a careful reading of the paper and helpful suggestions for improving it, as well as N. Boston, D. Cox, P. Gunnells and E. Markman for useful discussions. Finally, we thank the anonymous referee, whose comments led to several improvements in the exposition of our results.
