# NON-COMMUTATIVE MATRIX INTEGRALS AND REPRESENTATION VARIETIES OF SURFACE GROUPS IN A FINITE GROUP 

by Motohico MULASE (*) \& Josephine T. YU (**)

## 0 . Introduction.

The purpose of this paper is to establish Feynman diagram expansion formulas for non-commutative matrix integrals over a finite-dimensional real or complex von Neumann algebra. An interesting case is the real or complex group algebra of a finite group. Using the graphical expansion formulas, we give a new proof of the classical formulas for the number of homomorphisms from the fundamental group of a closed surface into a finite group, expressing the number in terms of irreducible representations of the finite group. Indeed, our integrals are generating functions for the cardinality of the representation variety of a surface group in a finite group.

The non-commutative matrix integrals of this article have their origin in random matrix theory (cf. [1], [7], [32], [51], [52]), and include real symmetric, complex hermitian, and quaternionic self-adjoint matrix integrals as a special case for a simple von Neumann algebra. Recently a surprising relation between random matrices and random permutations was discovered in [2], and was further studied from various points of view including representation theory of symmetric groups (cf. [3], [4], [8], [11], [25], [40], [41], [42]). Our theory exhibits yet another connection between matrix-type integrals and representation theory of finite groups.

[^0]Let $A$ be a finite-dimensional complex von Neumann algebra with the adjoint operation $*: A \rightarrow A$ and a linear map $\rangle: A \rightarrow \mathbb{C}$ called the trace. The algebra $A$ has a positive definite hermitian inner product defined by

$$
\langle a, b\rangle=\left\langle a b^{*}\right\rangle
$$

for $a, b \in A$. Let us choose an orthonormal basis $\left\{e_{1}, \ldots, e_{N}\right\}$ for $A$ with respect to the hermitian form, where $N=\operatorname{dim} A$. A ribbon graph is a graph with a cyclic order given at every vertex to incident half-edges. Recall that every ribbon graph $\Gamma$ defines a unique closed oriented surface $S_{\Gamma}$ on which $\Gamma$ is drawn and gives a cell-decomposition. Let $g(\Gamma)$ and $f(\Gamma)$ denote the genus of $S_{\Gamma}$ and the number of 2-cells, or faces, of the cell-decomposition, respectively. The Feynman diagram expansion formula we establish is the following:

$$
\begin{align*}
\log \int_{\left\{x \in A ; x=x^{*}\right\}} & \exp \left(-\frac{1}{2}\left\langle x^{2}\right\rangle\right) \exp \left(\sum_{j=1}^{\infty} \frac{t_{j}}{j}\left\langle x^{j}\right\rangle\right) \mathrm{d} \mu(x)  \tag{0.1}\\
= & \sum_{\substack{\Gamma \text { connected } \\
\text { ribbon graph }}} \frac{1}{\left|\operatorname{Aut}_{R}(\Gamma)\right|} A_{g(\Gamma), f(\Gamma)}^{\mathrm{or}} \prod_{j} t_{j}^{v_{j}(\Gamma)},
\end{align*}
$$

where $\mathrm{d} \mu(x)$ is a normalized Lebesgue measure on the real vector subspace of $A$ consisting of self-adjoint elements, $\operatorname{Aut}_{R}(\Gamma)$ is the ribbon graph automorphism group, and $v_{j}(\Gamma)$ is the number of $j$-valent vertices of the connected ribbon graph $\Gamma$. The integral of (0.1) is considered as a generating function of integrals

$$
\int_{\left\{x \in A ; x=x^{*}\right\}} \exp \left(-\frac{1}{2}\left\langle x^{2}\right\rangle\right) \prod_{j}^{\text {finite }}\left\langle x^{j}\right\rangle^{v_{j}} \mathrm{~d} \mu(x)
$$

for all finite sequences $\left(v_{1}, v_{2}, v_{3}, \ldots\right)$ of positive integers. The contribution of the graph $\Gamma$ in (0.1) is defined by

$$
A_{g, f}^{\mathrm{or}}=\sum_{\substack{i_{1}, \ldots, i_{g}, j_{1}, \ldots, j_{g} \\ h_{1}, \ldots, h_{f-1}=1}}^{N}\left\langle e_{i_{1}} e_{j_{1}} e_{i_{1}}^{*} e_{j_{1}}^{*} \cdots e_{i_{g}} e_{j_{g}} e_{i_{g}}^{*} e_{j_{g}}^{*} \cdot e_{h_{1}} e_{h_{1}}^{*} \cdots e_{h_{f-1}} e_{h_{f-1}}^{*}\right\rangle .
$$

We notice that the graph contribution $A_{g(\Gamma), f(\Gamma)}^{\mathrm{or}}$ depends only on the topological type of the surface $S_{\Gamma}$, which is the genus of the surface and the number of 2-cells in its cell-decomposition. If we apply (0.1) to a simple von Neumann algebra $A=M(n, \mathbb{C})$, then the formula recovers
the well-known graphical expansion formula for $n \times n$ hermitian matrix integrals found in many articles, including [6], [22], [27], [35], [40], [41], [43], [54]. The word non-commutative matrix integral in the title is justified because our von Neumann algebra can take the form $A=B \otimes M(n, \mathbb{C})$ with another von Neumann algebra $B$.

For a real von Neumann algebra $A$ with a real valued trace, our expansion formula is more complicated. Let us recall the notion of Möbius graph introduced in [38]. It is the non-orientable counterpart of ribbon graphs. A Möbius graph $\Gamma$ defines a unique unoriented surface $S_{\Gamma}$ and gives a cell-decomposition. Every closed non-orientable surface $S$ is obtained by removing $k$ disjoint disks from a sphere $S^{2}$ and gluing a cross-cap to each hole. The number of cross-caps is the cross-cap genus of the surface, and its Euler characteristic is given by $\chi(S)=2-k$. Every ribbon graph is an orientable Möbius graph, but it has a different automorphism group reflecting the fact that orientation-reversing map is allowed. Now the formula for a real von Neumann algebra is the following:
(0.2) $\log \int_{\left\{x \in A ; x=x^{*}\right\}} \exp \left(-\frac{1}{4}\left\langle x^{2}\right\rangle\right) \exp \left(\sum_{j=1}^{\infty} \frac{t_{j}}{2 j}\left\langle x^{j}\right\rangle\right) \mathrm{d} \mu(x)$

$$
\begin{aligned}
= & \sum_{\substack{\Gamma \text { connected orientable } \\
\text { Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} A_{g(\Gamma), f(\Gamma)}^{\mathrm{or}} \prod t_{j}^{v_{j}(\Gamma)} \\
& +\sum_{\substack{\Gamma \text { connected non- } \\
\text { orientable Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} A_{k(\Gamma), f(\Gamma)}^{\text {nor }} \prod_{j} t_{j}^{v_{j}(\Gamma)},
\end{aligned}
$$

where

$$
A_{k, f}^{\mathrm{nor}}=\sum_{\substack{i_{1}, \ldots, i_{k} \\ h_{1}, \ldots, h_{f-1}=1}}^{N}\left\langle e_{i_{1}}^{2} \cdots e_{i_{k}}^{2} \cdot e_{h_{1}}^{*} e_{h_{1}} \cdots e_{h_{f-1}}^{*} e_{h_{f-1}}\right\rangle,
$$

$\operatorname{Aut}_{M}(\Gamma)$ is the automorphism group of a graph $\Gamma$ as a Möbius graph, and $k(\Gamma)$ is the cross-cap genus of a non-orientable surface $S_{\Gamma}$. We notice the sharp contrast between $A_{g, f}^{\mathrm{or}}$ and $A_{k, f}^{\text {nor }}$, which reflects a particular choice of a presentation of the fundamental group $\pi_{1}\left(S_{\Gamma}\right)$ of a closed surface $S_{\Gamma}$. Every simple finite-dimensional real von Neumann algebra is a full matrix algebra over either the reals $\mathbb{R}$ or quaternions $\mathbb{H}$. We recover the graphical expansion formulas for real symmetric and quaternionic self-adjoint matrix integrals of $[9],[17],[38]$ from (0.2). An explicit computation is also carried out for real Clifford algebras [55].

Here we emphasize again that even though their expressions look dependent on a presentation of $\pi_{1}\left(S_{\Gamma}\right)$, the quantity $A_{g, f}^{\mathrm{or}}$ is an invariant of an orientable surface of topological type $(g, f)$, and $A_{k, f}^{\text {nor }}$ is an invariant of a non-orientable surface of topological type $(k, f)$. When the von Neumann algebra $A$ in our theory is simple, the invariants $A_{g, f}^{\text {or }}$ and $A_{k, f}^{\text {nor }}$ do not show any significance. The invariants become more interesting when the algebra is complicated. Now we notice that every finite-dimensional von Neumann algebra is semi-simple, and hence is decomposable into simple factors. When we apply the decomposition of $A$ into simple factors in the integral of (0.1) or (0.2), due to the logarithm in front of the integral, it becomes the sum of the integral for each simple factor. Therefore, any topological invariant given as $A_{g, f}^{\mathrm{or}}$ or $A_{k, f}^{\mathrm{nor}}$ is computable in terms of simple ones.

This idea can be concretely carried out for the real or complex group algebra of a finite group $G$. Using the complex group algebra $\mathbb{C}[G]$, we obtain

$$
\begin{align*}
& \log \int_{\left\{x \in \mathbb{C}[G] ; x=x^{*}\right\}} \exp \left(-\frac{1}{2} \chi_{\mathrm{reg}}\left(x^{2}\right)\right) \exp \left(\sum_{j} \frac{t_{j}}{j} \chi_{\mathrm{reg}}\left(x^{j}\right)\right) \mathrm{d} \mu(x)  \tag{0.3}\\
& \quad=\sum_{\substack{\Gamma \text { connected } \\
\text { ribbon graph }}} \frac{1}{\left|\operatorname{Aut}_{R} \Gamma\right|}|G|^{\chi\left(S_{\Gamma}\right)-1} \cdot\left|\operatorname{Hom}\left(\pi_{1}\left(S_{\Gamma}\right), G\right)\right| \cdot \prod_{j} t_{j}^{v_{j}(\Gamma)},
\end{align*}
$$

where $\chi\left(S_{\Gamma}\right)$ is the Euler characteristic of $S_{\Gamma}$, and $\chi_{\text {reg }}$ denotes the character of the regular representation of $G$ on $\mathbb{C}[G]$ linearly extended to the whole algebra. Notice that the formula gives a generating function for the cardinality of the representation variety $\operatorname{Hom}\left(\pi_{1}(S), G\right)$ of a closed oriented surface $S$ in the group $G$. With the real group algebra $\mathbb{R}[G]$ of $G$, we have

$$
\begin{align*}
& \log \int_{\left\{x \in \mathbb{R}[G] ; x=x^{*}\right\}} \exp \left(-\frac{1}{4} \chi_{\mathrm{reg}}\left(x^{2}\right)\right) \exp \left(\sum_{j} \frac{t_{j}}{2 j} \chi_{\mathrm{reg}}\left(x^{j}\right)\right) \mathrm{d} \mu(x)  \tag{0.4}\\
& =\sum_{\substack{\Gamma \text { connected } \\
\text { Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M} \Gamma\right|}|G|^{\chi\left(S_{\Gamma}\right)-1} \cdot\left|\operatorname{Hom}\left(\pi_{1}\left(S_{\Gamma}\right), G\right)\right| \cdot \prod_{j} t_{j}^{v_{j}(\Gamma)} .
\end{align*}
$$

Surprisingly, the RHS of (0.4) has the same expression as in (0.3), with the only difference being replacing ribbon graphs with Möbius graphs. These generating functions were reported in an earlier paper [39].

Let $G$ be a finite group and $\widehat{G}$ the set of equivalence classes of complex irreducible representations of $G$. The most fundamental formula
in representation theory of finite groups is the one that expresses the order of the group in terms of a square sum of the dimensions of irreducible representations of $G$ :

$$
\begin{equation*}
|G|=\sum_{\lambda \in \widehat{G}}(\operatorname{dim} \lambda)^{2} . \tag{0.5}
\end{equation*}
$$

The formula follows from the decomposition of the group algebra into irreducible fctors:

$$
\begin{equation*}
\mathbb{C}[G]=\bigoplus_{\lambda \in \widehat{G}} \operatorname{End}(\lambda) \tag{0.6}
\end{equation*}
$$

In 1978, Mednikh [31] discovered a remarkable generalization of the classical formula (0.5):

$$
\begin{equation*}
\sum_{\lambda \in \widehat{G}}(\operatorname{dim} \lambda)^{\chi(S)}=|G|^{\chi(S)-1} \cdot\left|\operatorname{Hom}\left(\pi_{1}(S), G\right)\right|, \tag{0.7}
\end{equation*}
$$

where $S$ is a compact Riemann surface. When $S=S^{2}$, (0.7) reduces to (0.5). Note that (0.6) is a von Neumann algebra isomorphism. Thus the integral of (0.3) over the self-adjoint elements of $\mathbb{C}[G]$ becomes the sum of hermitian matrix integrals. It is now easy to see that evaluation of the integral of (0.3) using (0.6) yields Mednykh's formula (0.7).

For a non-orientable surface $S$, the formula for the number of representations of $\pi_{1}(S)$ involves more detailed information on irreducible representations of $G$. Using the Frobenius-Schur indicator of irreducible characters [15], we decompose the set of complex irreducible representations $\widehat{G}$ into the union of three disjoint subsets, corresponding to real, complex, and quaternionic irreducible representations:

$$
\left\{\begin{array}{l}
\widehat{G}_{1}=\left\{\lambda \in \widehat{G} ; \frac{1}{|G|} \sum_{w \in G} \chi_{\lambda}\left(w^{2}\right)=1\right\}  \tag{0.8}\\
\widehat{G}_{2}=\left\{\lambda \in \widehat{G} ; \frac{1}{|G|} \sum_{w \in G} \chi_{\lambda}\left(w^{2}\right)=0\right\} \\
\widehat{G}_{4}=\left\{\lambda \in \widehat{G} ; \frac{1}{|G|} \sum_{w \in G} \chi_{\lambda}\left(w^{2}\right)=-1\right\}
\end{array}\right.
$$

The suffix 1,2 or 4 indicates the dimension of the base field $\mathbb{R}, \mathbb{C}$ or $\mathbb{H}$, respectively. In the fundamental paper of Frobenius and Schur [15] published in 1906, we find
(0.9) $\sum_{\lambda \in \widehat{G}_{1}}(\operatorname{dim} \lambda)^{\chi(S)}+\sum_{\lambda \in \widehat{G}_{4}}(-\operatorname{dim} \lambda)^{\chi(S)}=|G|^{\chi(S)-1} \cdot\left|\operatorname{Hom}\left(\pi_{1}(S), G\right)\right|$.

It is somewhat strange that a formula for non-orientable surfaces was known much earlier than its orientable counterpart. Actually, Frobenius and Schur obtained the formula as a counting formula for the number of group elements satisfying $x_{1}^{2} \cdots x_{k}^{2}=1$, but no relation to surface topology was in their motivation. If we take $S=\mathbb{R} P^{2}$, then the formula reduces to the well-known formula [24], [47]

$$
\sum_{\lambda \in \widehat{G}_{1}} \operatorname{dim} \lambda-\sum_{\lambda \in \widehat{G}_{4}} \operatorname{dim} \lambda=\text { the number of involutions of } G \text {. }
$$

The formula (0.9) immediately follows from the generating function (0.4) and the decomposition of $\mathbb{R}[G]$ into simple factors, which include real, complex, and quaternionic matrix algebras.

In a beautiful paper of Pierre van Moerbeke [52], we see the list of matrix-type integrals and the nonlinear integrable systems that characterize the integrals as functions on the potential. The simple von Neumann algebra integrals all fit into his scope. More general von Neumann algebra integrals of this article can be considered as a multi-matrix model with trivial interaction terms between matrices. They can be also interpreted as a matrix integral over an algebra different from $\mathbb{R}, \mathbb{C}$ and $\mathbb{H}$. In either point of view, we do not have any clear picture on the relation between our formulas (0.1), (0.2) and integrable equations. Since the generating functions for the Hurwitz numbers and the Gromov-Witten invariants of the Riemann surfaces are proven to satisfy integrable systems [41], [42], the integrability of the von Neumann algebra integrals seems to pose a condition on the structure of the algebra. However, the present article does not address this question.

The study of the volume of the representation variety $\operatorname{Hom}\left(\pi_{1}(S), G\right)$ of a surface group in a compact connected simply connected semi-simple Lie group is carried out by many authors including Witten [53], GrossTaylor [18], and Liu [28], [29], [30]. Although their focus was on the moduli space $\mathcal{M}(S, G)$ of flat $G$-connections on a closed surface $S$, through a relation

$$
\mathcal{M}(S, G)=\frac{\operatorname{Hom}\left(\pi_{1}(S), G\right)}{G / Z(G)}
$$

the study of moduli spaces is equivalent to that of representation varieties. Here $Z(G)$ is the center of the group $G$ that acts trivially on the representation variety through conjugation. It is interesting to note that exactly the same formulas (0.7) and (0.9) hold for a compact Lie group if the
infinite sum of LHS converges absolutely and the cardinality is interpreted as the volume of the variety in an appropriate sense. The naive extension of the method of this article does not work for the case of Lie groups, however, because the von Neumann algebra involved becomes infinite-dimensional and the integration (0.3) makes no sense.

The present paper is organized as follows. We review the notion of ribbon graphs and Möbius graphs in Section 1. Then in Section 2, we compute Feynman diagram expansion of integrals over a finite-dimensional complex von Neumann algebra in terms of ribbon graphs. Since integrals over a real von Neumann algebra behave differently, they are treated separately in Section 3. The generating functions for the number of representations of surface groups in a finite group are given in Section 4. As an application, we give a new proof of the formulas of Frobenius-Schur and Mednykh.

Acknowledgements. - The authors thank Michael Penkava and Andrew Waldron for discussions on non-commutative matrix integrals.

## 1. Ribbon graphs and Möbius graphs.

We review basic facts about graphs drawn on an orientable or nonorientable surface. Definition of the automorphism groups of these graphs is crutial when we use them to compute non-commutative matrix integrals. Graphs on an oriented surface are called ribbon or fat graphs. We refer to [6], [21], [22], [27], [40], [41], [42], [43], [54] for the use of ribbon/fat graphs in the study of moduli spaces of Riemann surfaces and related topics. The double line notation was first introduced in [50], generalizing the graphical expansion idea of [12]. Graphs on complex algebraic curves were studied from the quite different point of view of Grothendieck's dessins d'enfants [5], [20], [45], [46]. A relation between Strebel differentials [16], [49] and dessins d'enfants was studied in [37]. The terminology Möbius graph was introduced in [38] for a graph on a surface that is not oriented in order to avoid possible confusion, since ribbon or fat graphs are usually oriented. Graphs on an orientable or non-orientable surface are also called maps. Maps were studied mainly in the context of map coloring theorems [19], [44].

For a detailed treatment of ribbon graphs, we refer to the references cited above. Only a brief description is given here. A graph $\Gamma=(\mathcal{V}, \mathcal{E}, \iota)$
consists of a set of vertices $\mathcal{V}$, a set of edges $\mathcal{E}$, and an incidence relation

$$
\iota: \mathcal{E} \longrightarrow(\mathcal{V} \times \mathcal{V}) / \mathfrak{S}_{2}
$$

Following [37], let us introduce the edge refinement $\Gamma_{\mathcal{E}}$ of a graph $\Gamma$, which is the original graph together with a two-valent vertex (the midpoint) chosen from each edge. A half-edge of $\Gamma$ is an edge of its edge refinement. A ribbon graph is a graph with a cyclic order assigned at each vertex to the set of half-edges incident to the vertex. When a cyclic order is given, a vertex can be placed on an oriented plane, and half-edges incident to the vertex can be represented by double lines. The orientation of the plane gives an orientation of the ribbon-like structure, and its boundaries inherit a compatible orientation (see Figure 1.1).

Figure 1.1. A vertex with a cyclic order given to incident half-edges. It is placed on a plane with the clockwise orientation. The half-edges become crossroads with a compatible orientation at the boundary.

Figure 1.2. A ribbon graph is obtained by connecting cyclically ordered vertices with a ribbon like edge preserving the orientation.

A topological realization of a ribbon graph $\Gamma$ is obtained by connecting these half-edges in an orientation-compatible manner. Since each boundary has a well-defined orientation, we can attach an oriented disk to the boundary and form a compact oriented surface $S_{\Gamma}$. Let $f(\Gamma)$ denote the number of disks attached. This number is uniquely determined by the ribbon graph structure of a graph. The attached disks, together with the vertices and edges of $\Gamma$, form a cell-decomposition of the surface $S_{\Gamma}$. The genus of the surface is determined by the formula for the Euler characteristic

$$
\begin{equation*}
\chi\left(S_{\Gamma}\right)=2-2 g\left(S_{\Gamma}\right)=v(\Gamma)-e(\Gamma)+f(\Gamma), \tag{1.1}
\end{equation*}
$$

where $v(\Gamma)=|\mathcal{V}|$ is the number of vertices and $e(\Gamma)=|\mathcal{E}|$ the number of edges of $\Gamma$.

Conversely, if a connected graph $\Gamma$ is drawn on an oriented surface $S$ in a way that $S \backslash \Gamma$ is the union of disjoint open disks, then $\Gamma$ is a ribbon graph that defines a cell-decomposition of $S$. The cyclic order of halfedges incident to a vertex is determined by the orientation of the surface (see Figure 1.3). Obviously we have $S=S_{\Gamma}$.

Figure 1.3. A graph drawn on an oriented surface. At each vertex, the orientation of the surface determines a cyclic order of the edges incident to the vertex.

Definition (see [37]). - Let $\Gamma$ be a ribbon graph. The group $\operatorname{Aut}_{R} \Gamma$ of automorphisms of $\Gamma$ consists of graph automorphisms of the edge refinement $\Gamma_{\mathcal{E}}$ that preserves the cyclic order at each vertex of $\Gamma$.

In a ribbon graph, an edge connects two oriented vertices in the orientation-compatible manner. If we connect vertices without paying attention to the orientation, then we obtain a Möbius graph. An edge connecting two oriented vertices is not twisted if the connection is consistent with the orientation, and is twisted otherwise. Thus a double twist is the same as no twist. A new operation allowed in a Möbius graph that preserves the Möbius graph structure is a vertex flip at a vertex. This operation reverses the cyclic order assigned at the vertex, and twists every half-edge incident to the vertex (see Figure 1.4). If an edge is incident to a vertex and forms a loop, then the vertex flip at this vertex does not change the twist of the edge.

We can formalize the definition of a Möbius graph in the following way.

Definition 1.2. - A Möbius graph is the equivalence class of ribbon graphs with a $\mathbb{Z} / 2 \mathbb{Z}$-color assigned to each edge. Two edge-colored ribbon graphs are equivalent if one is obtained from the other by a sequence of vertex flip operations. A vertex flip reverses the cyclic order of a vertex

Figure 1.4. A vertex flip operation. It reverses the cyclic order at a vertex, and gives an extra twist to each half-edge incident to the vertex.
and the color of each half-edge incident to it. The group $\operatorname{Aut}_{M} \Gamma$ of automorphisms of a Möbius graph consists of graph automorphisms of the edge refinement of the underlying graph $\Gamma$ that preserve the equivalence class of the edge-colored ribbon graph.

Figure 1.5. A Möbius graph.
A topological realization of a Möbius graph is the realization of the $\mathbb{Z} / 2 \mathbb{Z}$-color of each edge as a twist or non-twist. Each boundary component of a Möbius graph is a circle, without any consistent orientation. By attaching an open disk to each boundary circle, a Möbius graph gives rise to a closed surface without orientation. Let us denote this surface by $S_{\Gamma}$ and by $f(\Gamma)$ the number of disks, as before. We note that $\Gamma$ defines a cell-decomposition of $S_{\Gamma}$. Every closed non-orientable surface is constructed by removing $k$ disks from a sphere and attaching a cross-cap at each hole. The number $k$ is the cross-cap genus of the surface, and the Euler characteristic of the surface is given by $2-k$. If the surface $S_{\Gamma}$ is non-orientable, then we have

$$
\begin{equation*}
\chi\left(S_{\Gamma}\right)=2-k\left(S_{\Gamma}\right)=v(\Gamma)-e(\Gamma)+f(\Gamma) . \tag{1.2}
\end{equation*}
$$

A ribbon graph $\Gamma$ is also a Möbius graph. If $\Gamma$ and its flip $\Gamma^{t}$ (the graph obtained by applying the vertex flip operation at every vertex
simultaneously) is the same ribbon graph, then we have

$$
\begin{equation*}
\left|\operatorname{Aut}_{M} \Gamma\right|=2\left|\operatorname{Aut}_{R} \Gamma\right| . \tag{1.3}
\end{equation*}
$$

Otherwise, $\Gamma$ and $\Gamma^{t}$ are different ribbon graphs but the same as a Möbius graph, and we have

$$
\begin{equation*}
\operatorname{Aut}_{M} \Gamma \cong \operatorname{Aut}_{R} \Gamma \tag{1.4}
\end{equation*}
$$

## 2. Integrals over a finite-dimensional complex von Neumann algebra.

We define the integrals over a finite-dimensional complex von Neumann algebra that we study, and establish their graphical expansion formulas in terms of ribbon graphs.

Definition 2.1. - A finite-dimensional complex von Neumann algebra is a finite-dimensional $\mathbb{C}$-algebra with a conjugate-linear anti-isomorphism $*: A \rightarrow A$ and a $\mathbb{C}$-linear map called trace $\rangle:$ Aarrow $\mathbb{C}$ that satisfy the following conditions for every $a, b \in A$ :

$$
\begin{cases}\left(a^{*}\right)^{*}=a, & (a b)^{*}=b^{*} a^{*}  \tag{2.1}\\ \left\langle a^{*}\right\rangle=\overline{\langle a\rangle}, & \langle a b\rangle=\langle b a\rangle \\ \langle 1\rangle=1, & \left\langle a a^{*}\right\rangle>0, a \neq 0\end{cases}
$$

If $A$ is an $\mathbb{R}$-algebra with a real valued trace, then it is called a real von Neunamm algebra.

To avoid confusion, we only deal with complex von Neumann algebras in this section. Real ones are considered in Section 3. A finite-dimensional von Neumann algebra $A$ is a real vector space with a non-degenerate hermitian inner product defined by

$$
\begin{equation*}
\langle a, b\rangle=\left\langle a b^{*}\right\rangle . \tag{2.2}
\end{equation*}
$$

As usual, an invertible linear transformation of $A$ that preserves the hermitian form is called a unitary transformation. We denote by $U(A)$ the group of unitary transformations of $A$. A real vector subspace of $A$ consisting of self-adjoint elements

$$
\begin{equation*}
\mathcal{H}_{A}=\left\{a \in A ; a^{*}=a\right\} \tag{2.3}
\end{equation*}
$$

is of our particular interest. We note that $\mathcal{H}_{A}$ is invariant under the conjugation action of $U(A)$. Let us denote by $d x$ the translation invariant Lebesgue measure of the real vector space $\mathcal{H}_{A}$ that is also invariant under the conjugation action of $U(A)$. We notice that the quadratic form $\left\langle x^{2}\right\rangle$ is positive definite on the space $\mathcal{H}_{A}$ of self-adjoint elements. We denote by

$$
\begin{equation*}
\mathrm{d} \mu(x)=\frac{\mathrm{d} x}{\int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2}\left\langle x^{2}\right\rangle} \mathrm{d} x} \tag{2.4}
\end{equation*}
$$

the normalized Lebesgue measure on $\mathcal{H}_{A}$.
Our subject of study is the following integral

$$
\begin{equation*}
\prod_{j=1}^{n} \frac{1}{v_{j}!\cdot j^{v_{j}}} \int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2}\left\langle x^{2}\right\rangle} \prod_{j=1}^{n}\left\langle x^{j}\right\rangle v_{j} \mathrm{~d} \mu(x) \tag{2.5}
\end{equation*}
$$

for every $n$-tuple of positive integers $\left(v_{1}, \ldots, v_{n}\right) \in \mathbb{N}^{n}, n=0,1,2, \ldots$ The constant factor in front of the integral is placed for a combinatorial reason explained later in this section. To consider a generating function of these integrals, it is more convenient to introduce

$$
\begin{equation*}
\mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)=\sum_{j \geq 1} j v_{j} \tag{2.6}
\end{equation*}
$$

and the sum of the integrals over all elements of

$$
\mathbb{N}^{\infty}=\underset{n}{\lim _{\longrightarrow}} \mathbb{N}^{n}=\left\{\left(v_{1}, v_{2}, v_{3}, \ldots\right) ; v_{j}=0 \text { for } j \gg 0\right\}
$$

with a fixed value of $\mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)$. Notice that for every finite value of $n$,

$$
\left(v_{1}, v_{2}, v_{3}, \ldots\right) \in \mathbb{N}^{n} \quad \text { if } \quad \mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right) \leq n
$$

Thus let us define

$$
\begin{align*}
Z_{A}^{\mathbb{C}}\left(t_{1}, t_{2}, t_{3}, \ldots\right)=\sum_{n=0}^{\infty} & \sum_{\substack{\left(v_{1}, v_{2}, v_{3}, \ldots\right) \in \mathbb{N}^{\infty} \\
\mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)=n}}  \tag{2.7}\\
& \prod_{j \geq 1}^{\text {finite }} \frac{t_{j}^{v_{j}}}{v_{j}!\cdot j^{v_{j}}} \int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2}\left\langle x^{2}\right\rangle} \prod_{j \geq 1}^{\text {finite }}\left\langle x^{j}\right\rangle^{v_{j}} \mathrm{~d} \mu(x),
\end{align*}
$$

where $t_{1}, t_{2}, t_{3}, \ldots$ are expansion parameters carrying the weight

$$
\begin{equation*}
\operatorname{deg} t_{j}=j \tag{2.8}
\end{equation*}
$$

The monomial $\prod_{j} t_{j}^{v_{j}}$ for every $\left(v_{1}, v_{2}, v_{3}, \ldots\right)$ satisfying $\mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)=n$ has weighted homogeneous degree $n$ by (2.6) and (2.8). Hence (2.7) is an infinite sum of weighted homogeneous polynomials of degree $n$ for every $n \geq 0$.

Symbolically, we can write the generating function in an integral form

$$
\begin{equation*}
Z_{A}^{\mathbb{C}}(t)=\int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2}\left\langle x^{2}\right\rangle} \mathrm{e}^{\sum_{j=1}^{\infty} t_{j} / j\left\langle x^{j}\right\rangle^{v_{j}}} \mathrm{~d} \mu(x) . \tag{2.9}
\end{equation*}
$$

As an actual integral, (2.9) is ill-defined because of the infinite sum in the exponent. There is a way to make it well-defined so that (2.7) is a rigorous asymptotic expansion of (2.9). Since we do not employ this point of view in this paper, we refer to [35], [36] for more detail, and work on the expansion form only.

Let $\left\{e_{1}, \ldots, e_{N}\right\}$ be an orthonormal basis for $A$ with respect to the hermitian form (2.2), where $N=\operatorname{dim}_{\mathbb{C}} A$. Since

$$
\left\langle e_{i}, e_{j}\right\rangle=\left\langle e_{i} e_{j}^{*}\right\rangle=\left\langle e_{j}^{*}\left(e_{i}^{*}\right)^{*}\right\rangle=\left\langle e_{j}^{*}, e_{i}^{*}\right\rangle
$$

$\left\{e_{1}^{*}, \ldots, e_{N}^{*}\right\}$ also forms an orthonormal basis for $A$. For every $a \in A$ we have

$$
\begin{equation*}
a=\sum_{j=1}^{N}\left\langle a, e_{j}\right\rangle e_{j}=\sum_{j=1}^{N}\left\langle a, e_{j}^{*}\right\rangle e_{j}^{*} . \tag{2.10}
\end{equation*}
$$

Equivalently,

$$
\begin{equation*}
\langle a, b\rangle=\sum_{j=1}^{N}\left\langle a, e_{j}\right\rangle \cdot\left\langle e_{j}, b\right\rangle=\sum_{j=1}^{N}\left\langle a, e_{j}^{*}\right\rangle \cdot\left\langle e_{j}^{*}, b\right\rangle \tag{2.11}
\end{equation*}
$$

holds for every $a, b \in A$.

Lemma 2.2. - Choose two elements

$$
x=\sum_{i=1}^{N} x_{i} e_{i} \quad \text { and } \quad y=\sum_{i=1}^{N} y_{i} e_{i}
$$

of $A$, and consider $\mathrm{e}^{\langle x y\rangle}$ as a function in $2 N$ variables

$$
\left(x_{1}, \ldots, x_{N}, y_{1}, \ldots, y_{N}\right) \in \mathbb{C}^{2 N}
$$

TOME 55 (2005), FASCICULE 6

With respect to the differential operator

$$
\begin{equation*}
\frac{\partial}{\partial y}=\sum_{i=1}^{N} \frac{\partial}{\partial y_{i}} e_{i}^{*} \tag{2.12}
\end{equation*}
$$

we have

$$
\begin{equation*}
\frac{\partial}{\partial y} \mathrm{e}^{\langle x y\rangle}=x \mathrm{e}^{\langle x y\rangle} \tag{2.13}
\end{equation*}
$$

In particular,

$$
\begin{equation*}
\left\langle\left(\frac{\partial}{\partial y}\right)^{j}\right\rangle^{m} \mathrm{e}^{\langle x y\rangle}=\left\langle x^{j}\right\rangle^{m} \mathrm{e}^{\langle x y\rangle} \tag{2.14}
\end{equation*}
$$

for every $j, m>0$.
Proof. - By definition,

$$
\begin{aligned}
\frac{\partial}{\partial y} \mathrm{e}^{\langle x y\rangle} & =\sum_{i} \frac{\partial}{\partial y_{i}} e_{i}^{*} \exp \left(\left\langle\sum_{j} x_{j} e_{j} \sum_{k} y_{k} e_{k}\right\rangle\right) \\
& =\sum_{i} \sum_{j} x_{j}\left\langle e_{j} e_{i}\right\rangle e_{i}^{*} \mathrm{e}^{\langle x y\rangle} \\
& =\sum_{j} x_{j} \sum_{i}\left\langle e_{j}, e_{i}^{*}\right\rangle e_{i}^{*} \mathrm{e}^{\langle x y\rangle}=\sum_{j} x_{j} e_{j} \mathrm{e}^{\langle x y\rangle}=x \mathrm{e}^{\langle x y\rangle} .
\end{aligned}
$$

Using the linearity of the trace and (2.13) repeatedly, we obtain (2.14).
Lemma 2.3. - Let $A$ be a finite-dimensional complex von Neumann algebra. Then we have the following Laplace transform formula for (2.5):

$$
\begin{equation*}
\int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2}\left\langle x^{2}\right\rangle} \prod_{j=1}^{n}\left\langle x^{j}\right\rangle^{v_{j}} \mathrm{~d} \mu(x)=\left.\prod_{j=1}^{n}\left\langle\left(\frac{\partial}{\partial y}\right)^{j}\right\rangle^{v_{j}} \mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}\right|_{y=0} . \tag{2.15}
\end{equation*}
$$

Proof. - For $y \in A$ of Lemma 2.2, its adjoint is given by

$$
y^{*}=\sum_{i=1}^{N} \bar{y}_{i} e_{i}^{*}
$$

Note that $\partial y^{*} / \partial y=0$ since $\partial \bar{y}_{i} / \partial y_{j}=0$ for any $i$ and $j$. Now Lemma 2.2 yields

$$
\int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2}\left\langle x^{2}\right\rangle}\left\langle x^{j}\right\rangle^{m} \mathrm{~d} \mu(x)=\left.\left\langle\left(\frac{\partial}{\partial y}\right)^{j}\right\rangle^{m} \int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2}\left\langle x^{2}\right\rangle} \mathrm{e}^{\left\langle x\left(y+y^{*}\right)\right\rangle} \mathrm{d} \mu(x)\right|_{y=0}
$$

Since $y+y^{*} \in \mathcal{H}_{A}$ and $\mathrm{d} \mu(x)$ is a translational invariant measure, we have

$$
\begin{aligned}
\int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2}\left\langle x^{2}\right\rangle} \mathrm{e}^{\left\langle x\left(y+y^{*}\right)\right\rangle} \mathrm{d} \mu(x) & =\int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2}\left\langle\left(x-\left(y+y^{*}\right)\right)^{2}\right\rangle} \mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle} \mathrm{d} \mu(x) \\
& =\mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}
\end{aligned}
$$

Equation (2.15) follows from these formulas.

In the same way as in the proof of Lemma 2.2 , we obtain

$$
\begin{aligned}
\frac{\partial}{\partial y} \mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle} & =\sum_{i} \frac{\partial}{\partial y_{i}} e_{i}^{*} \mathrm{e}^{\frac{1}{2}\left\langle\left(\Sigma_{j} y_{j} e_{j}+\Sigma_{j} \bar{y}_{j} e_{j}^{*}\right)^{2}\right\rangle} \\
& =\sum_{i}\left\langle\left(y+y^{*}\right) e_{i}\right\rangle e_{i}^{*} \mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle} \\
& =\sum_{i}\left\langle y+y^{*}, e_{i}^{*}\right\rangle e_{i}^{*} \mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle} \\
& =\left(y+y^{*}\right) \mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}
\end{aligned}
$$

In particular,

$$
\frac{\partial}{\partial y_{i}} \mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}=\left\langle y+y^{*}, e_{i}^{*}\right\rangle \mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}
$$

and hence

$$
\begin{align*}
\left.\frac{\partial}{\partial y_{i}} \frac{\partial}{\partial y_{j}} \mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}\right|_{y=0} & =\left.\frac{\partial}{\partial y_{i}}\left\langle y+y^{*}, e_{j}^{*}\right\rangle\right|_{y=0}  \tag{2.16}\\
& =\left\langle e_{i}, e_{j}^{*}\right\rangle=\left\langle e_{i} e_{j}\right\rangle
\end{align*}
$$

Our purpose is to compute

$$
\begin{equation*}
\left.\sum_{\substack{\left(v_{1}, v_{2}, v_{3}, \ldots\right) \in \mathbb{N}^{\infty} \\ \mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)=n}} \prod_{j \geq 1}^{\text {finite }} \frac{1}{v_{j}!\cdot j^{v_{j}}}\left\langle\left(\frac{\partial}{\partial y}\right)^{j}\right\rangle^{v_{j}} \mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}\right|_{y=0} \tag{2.17}
\end{equation*}
$$

To this end, first we observe

$$
\begin{equation*}
\left\langle\left(\frac{\partial}{\partial y}\right)^{j}\right\rangle=\sum_{i_{1}, \ldots, i_{j}} \frac{\partial}{\partial y_{i_{1}}} \cdots \frac{\partial}{\partial y_{i_{j}}}\left\langle e_{i_{1}}^{*} \cdots e_{i_{j}}^{*}\right\rangle \tag{2.18}
\end{equation*}
$$

Notice that $\left\langle e_{i_{1}}^{*} \cdots e_{i_{j}}^{*}\right\rangle$ is invariant under cyclic permutations. For every factor (2.18) of (2.17), let us assign a $j$-valent vertex with $j$ half-edges incident to it, with a cyclic order of these half-edges. Every half-edge corresponds to an index $i_{k}, k=1, \ldots, j$, and we assign $e_{i_{k}}^{*} \in A$ to this half-edge. We then assign $\left\langle e_{i_{1}}^{*} \cdots e_{i_{j}}^{*}\right\rangle$ to this vertex (see Figure 2.1).

Figure 2.1. A j-valent vertex with a cyclic order given to incident halfedges. Each half-edge is labeled by $i_{k}$, and an element $e_{i_{k}}^{*}$ is assigned.

For every $j=1,2,3, \ldots$, we draw $v_{j} j$-valent vertices with $\left\langle e_{i_{1}}^{*} \cdots e_{i_{j}}^{*}\right\rangle$ assigned. Every vertex has $j$ degrees of freedom coming from cyclic rotations. This redundancy is compensated by the factor $j^{v_{j}}$ in (2.17). The redundancy of permuting $v_{j}$ vertices of the same valence $j$ is compensated by $v_{j}$ ! in (2.17). To indicate the effect of (2.16), we connect two half-edges according to the paired differentiation. We notice that since we set $y=0$ after differentiation, no term in (2.17) survives unless all differentiations are paired as in (2.16). When we connect a half-edge labeled by $i_{k}$ at one vertex with another half-edge labeled by $h_{\ell}$, we assign $\left\langle e_{i_{k}} e_{h_{\ell}}\right\rangle$ to this edge (see Figure 2.2). This quantity is called the propagator of the edge. Notice that the propagator is symmetric

$$
\begin{equation*}
\left\langle e_{i_{k}} e_{h_{\ell}}\right\rangle=\left\langle e_{h_{\ell}} e_{i_{k}}\right\rangle \tag{2.19}
\end{equation*}
$$

and hence we do not have any particular direction on our edge.

Figure 2.2. A half-edge labeled by $i_{3}$ of the left vertex is connected with a half-edge labeled by $j_{4}$ of the vertex at the right. A propagator $\left\langle e_{i_{3}} e_{j_{4}}\right\rangle$ is assigned to this edge.

Here we have to be cautious when two vertices are connected. For example, the connection described in Figure 2.2 preserves the cyclic orders of two vertices. An edge is connecting two vertices in the orientationpreserving manner if the cyclic orders of the two vertices agree when the edge is shrunk to a point and the two vertices are put together. Otherwise, the edge is orientation-reversing. All connections we make in this section should be orientation-preserving. When all half-edges are paired and connected in the orientation-preserving manner, we obtain a ribbon graph $\Gamma$. It is easy to see that the compensation of rotations around each vertex and permutations of vertices of the same valence leads to the factor of $1 /\left|\operatorname{Aut}_{R}(\Gamma)\right|$ coming from the automorphism of $\Gamma$ (see [36], [37]). The quantity $v_{j}$ represents the number of $j$-valent vertices of $\Gamma$ by the construction. Thus

$$
\begin{equation*}
v(\Gamma)=\sum_{j} v_{j} \quad \text { and } \quad e(\Gamma)=\frac{1}{2} \sum_{j} j v_{j} \tag{2.20}
\end{equation*}
$$

represent the total number of vertices and edges of $\Gamma$, respectively. Notice the combinatorial constraint

$$
2 e(\Gamma)=\mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right),
$$

which comes from the fact that unless every half-edge is paired with another one to form an edge of a ribbon graph, the corresponding contribution of $\left(v_{1}, v_{2}, v_{3}, \ldots\right)$ in the sum of (2.17) is 0 . Summarizing, we have

Proposition 2.4. - Let $R G(e)$ denote the set of all ribbon graphs, may or may not be connected, consisting of a total of e edges. The number of $j$-valent vertices of $\Gamma \in R G(e)$ is denoted by $v_{j}=v_{j}(\Gamma)$. For each $j$-valent vertex of $\Gamma$, let us assign $\left\langle e_{i_{1}}^{*} \cdots e_{i_{j}}^{*}\right\rangle$. For every edge we assign $\left\langle e_{i_{k}} e_{h_{\ell}}\right\rangle$, so that the incidence relation is consistent with the relation described above, namely, this edge connects the half-edge labeled by $i_{k}$ of a vertex to the half-edge labeled by $h_{\ell}$ from another vertex, which could be the same vertex. Let $A_{\Gamma}^{\text {or }}$ denote the sum with respect to all indices of the product of all contributions from vertices and edges. Then we have

$$
\begin{align*}
& \sum_{\substack{\left(v_{1}, v_{2}, v_{3}, \ldots\right) \in \mathbb{N}^{\infty} \\
\mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)=2 e}} \int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2}\left\langle x^{2}\right\rangle} \prod_{j \geq 1}^{\text {finite }} \frac{1}{v_{j}!\cdot j^{v_{j}}}\left\langle x^{j}\right\rangle^{v_{j}} \mathrm{~d} \mu(x)  \tag{2.21}\\
& \quad=\left.\sum_{\substack{\left(v_{1}, v_{2}, v_{3}, \ldots\right) \in \mathbb{N}^{\infty} \\
\mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)=2 e}} \prod_{j \geq 1}^{\text {finite }} \frac{1}{v_{j}!\cdot j^{v_{j}}}\left\langle\left(\frac{\partial}{\partial y}\right)^{j}\right\rangle^{v_{j}} \mathrm{e}^{\frac{1}{2}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}\right|_{y=0} \\
& \quad=\sum_{\Gamma \in R G(e)} \frac{1}{\left|\operatorname{Aut}_{R}(\Gamma)\right|} A_{\Gamma}^{\mathrm{or}},
\end{align*}
$$

where $\operatorname{Aut}_{R}(\Gamma)$ is the automorphism group of ribbon graph $\Gamma$ defined in Section 1.

Therefore, to evaluate the integral, it suffices to calculate $A_{\Gamma}^{\text {or }}$ for each ribbon graph $\Gamma$. A key fact is the following.

Lemma 2.5. - Let $\Gamma$ be a connected ribbon graph with two or more vertices, and $E$ an edge of $\Gamma$ incident to two distinct vertices. Then the contribution of the graph $A_{\Gamma}^{\text {or }}$ is invariant under the edge-contraction:

$$
\begin{equation*}
A_{\Gamma}^{\mathrm{or}}=A_{\Gamma / E}^{\mathrm{or}} \tag{2.22}
\end{equation*}
$$

where $\Gamma / E$ denotes the ribbon graph obtained by shrinking $E$ to a point in $\Gamma$ and joining the two incident vertices together.

Remark. - This invariance is found in many literatures including [53]. Witten uses the invariance to calculate quantum Yang-Mills theory over a Riemann surface by approximation through lattice gauge theory. It appears also in [38].

Proof. - Let $V_{1}$ and $V_{2}$ be the two vertices of $\Gamma$ incident to $E$. The contribution from $V_{1}$ can be written as $\left\langle a e_{i}^{*}\right\rangle$ and that from $V_{2}$ as $\left\langle e_{j}^{*} b\right\rangle$, where $a$ and $b$ are products of the basis elements $e_{k}^{*}$ of the von Neumann algebra $A$. The invariance of the edge contraction is local, and comes down to the following computation:

$$
\begin{align*}
\sum_{i, j}\left\langle a e_{i}^{*}\right\rangle \cdot\left\langle e_{i} e_{j}\right\rangle \cdot\left\langle e_{j}^{*} b\right\rangle & =\sum_{i, j}\left\langle a, e_{i}\right\rangle \cdot\left\langle e_{i}, e_{j}^{*}\right\rangle \cdot\left\langle e_{j}^{*}, b^{*}\right\rangle  \tag{2.23}\\
& =\left\langle a, b^{*}\right\rangle=\langle a b\rangle
\end{align*}
$$

The quantity $\langle a b\rangle$ is exactly the contribution of the new vertex obtained by joining $V_{1}$ and $V_{2}$.

Every connected ribbon graph $\Gamma$ gives rise to an oriented surface $S_{\Gamma}$ whose Euler characteristic is determined by

$$
\chi\left(S_{\Gamma}\right)=2-2 g\left(S_{\Gamma}\right)=v(\Gamma)-e(\Gamma)+f(\Gamma)
$$

The graph defines a cell-decomposition of $S_{\Gamma}$. The topological type of $\Gamma$ is $(g, f)$, the genus of the surface and the number of faces of its celldecomposition. Note that since the edge contraction operation decreases $v(\Gamma)$ and $e(\Gamma)$ by one and preserves the number of faces, the topological type is preserved. A theorem of topology states that if $\Gamma_{1}$ and $\Gamma_{2}$ are two connected ribbon graphs with the same topological type, then by consecutive applications of edge contraction and its inverse operation (edge expansion), $\Gamma_{1}$ can be brought to $\Gamma_{2}$ (see [23]). Therefore, to compute $A_{\Gamma}^{\text {or }}$, we can use our favorite graph of the same topological type, for example, a graph of Figure 2.3.

Figure 2.3. A standard graph of topological type ( $g, f$ ). It has $f-1$ tadpoles on the left, and $g$ bi-petal flowers on the right.

Proposition 2.6. - Let $A_{g, f}^{\mathrm{or}}$ denote the contribution of the standard graph of Figure 2.3. Then

$$
\begin{equation*}
A_{g, f}^{\mathrm{or}}=\sum_{\substack{i_{1}, \ldots, i_{g} ; j_{1}, \ldots, j_{g} \\ h_{1}, \ldots, h_{f-1}}}^{N}\left\langle e_{i_{1}} e_{j_{1}} e_{i_{1}}^{*} e_{j_{1}}^{*} \cdots e_{i_{g}} e_{j_{g}} e_{i_{g}}^{*} e_{j_{g}}^{*} .\right. \tag{2.24}
\end{equation*}
$$

Proof. - By definition,

$$
\begin{aligned}
& A_{g, f}^{\mathrm{or}}=\sum_{\substack{i_{1}, \ldots, i_{g} ; j_{1}, \ldots, j_{g} \\
a_{1}, \ldots, a_{g} ; b_{1}, \ldots, b_{g} \\
k_{1}, \ldots, k_{f-1} ; h_{1}, \ldots, h_{f-1}}}\left\langle e_{a_{1}}^{*} e_{b_{1}}^{*} e_{i_{1}}^{*} e_{j_{1}}^{*} \cdots e_{a_{g}}^{*} e_{b_{g}}^{*} e_{i_{g}}^{*} e_{j_{g}}^{*} \cdot e_{h_{1}}^{*} e_{k_{1}}^{*} \cdots e_{h_{f-1}}^{*} e_{k_{f-1}}^{*}\right\rangle \\
& \times\left\langle e_{a_{1}} e_{i_{1}}\right\rangle\left\langle e_{b_{1}} e_{j_{1}}\right\rangle \cdots\left\langle e_{a_{g}} e_{i_{g}}\right\rangle\left\langle e_{b_{g}} e_{j_{g}}\right\rangle \\
& \times\left\langle e_{h_{1}} e_{k_{1}}\right\rangle \cdots\left\langle e_{h_{f-1}} e_{k_{f-1}}\right\rangle .
\end{aligned}
$$

Using cyclic invariance of the trace and (2.11), the desired formula (2.24) follows.

The generating function $Z_{A}^{\mathbb{C}}(t)$ of (2.7) is expanded in terms of all ribbon graphs, connected or non-connected. Since $Z_{A}^{\mathbb{C}}(0)=1$, the formal logarithm is well-defined for $Z_{A}^{\mathbb{C}}(t)$. The graphical expansion of $\log Z_{A}^{\mathbb{C}}(t)$ then consists of connected ribbon graphs.

Theorem 2.7. - The graphical expansion of the logarithm of the generating function $Z_{A}^{\mathbb{C}}(t)$ of (2.7) is given by

$$
\begin{align*}
\log Z_{A}^{\mathbb{C}}(t) & =\log \int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2}\left\langle x^{2}\right\rangle} \mathrm{e}^{\Sigma_{j} t_{j} / j\left\langle x^{j}\right\rangle} \mathrm{d} \mu(x)  \tag{2.25}\\
& =\sum_{\substack{\Gamma \text { connected } \\
\text { ribbon graph }}} \frac{1}{\left|\operatorname{Aut}_{R}(\Gamma)\right|} A_{g(\Gamma), f(\Gamma)}^{\text {or }} \prod_{j} t_{j}^{v_{j}(\Gamma)} .
\end{align*}
$$

Recall the graph theoretic formulas (2.20). If we change $t_{j}$ to $\beta t_{j}$, then the graph expansion receives an extra factor of $\beta^{v(\Gamma)}$ in the contribution from $\Gamma$. If we change $\mathrm{e}^{-\frac{1}{2}\left\langle x^{2}\right\rangle}$ to $\mathrm{e}^{-\frac{1}{2} \alpha\left\langle x^{2}\right\rangle}$ with a positive real number $\alpha$, then a change of variable $x \mapsto x / \sqrt{\alpha}$ produces a factor $\alpha^{-e(\Gamma)}$ to the $\Gamma$ contribution. Therefore,

$$
\begin{align*}
& \log \int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{2} \alpha\left\langle x^{2}\right\rangle} \mathrm{e}^{\beta \Sigma_{j} t_{j} / j\left\langle x^{j}\right\rangle} \mathrm{d} \mu_{\alpha}(x)  \tag{2.26}\\
&=\sum_{\substack{\Gamma \text { connected } \\
\text { ribbon graph }}} \frac{\alpha^{-e(\Gamma)} \beta^{v(\Gamma)}}{\left|\operatorname{Aut}_{R}(\Gamma)\right|} A_{g(\Gamma), f(\Gamma)}^{\mathrm{or}} \prod_{j} t_{j}^{v_{j}(\Gamma)},
\end{align*}
$$

where the normalized Lebesgue measure is adjusted for $\mathrm{e}^{-\frac{1}{2} \alpha\left\langle x^{2}\right\rangle}$. An important example of Theorem 2.7 is a hermitian matrix integral.

Example 2.1. - Let us apply (2.25) to a complex matrix algebra $A=M(n, \mathbb{C})$. The $*$-operation on this algebra is the matrix adjoint, and

$$
\begin{equation*}
\langle X\rangle=\frac{1}{n} \operatorname{tr} X \tag{2.27}
\end{equation*}
$$

is the normalized trace. The space of self-adjoint elements is the set of hermitian matrices:

$$
\mathcal{H}_{M(n, \mathbb{C})}=\mathcal{H}_{n, \mathbb{C}} .
$$

As an orthonormal basis, we use $\left\{\sqrt{n} e_{i j}\right\}$, where

$$
e_{i j}=\left[\delta_{i \alpha} \delta_{j \beta}\right]_{\alpha, \beta}
$$

is the $n \times n$ elementary matrix which has 1 at its $i j$ entry and 0 everywhere else. Then we have

$$
\begin{align*}
& \log \int_{\mathcal{H}_{n, \mathrm{C}}} \mathrm{e}^{-\frac{1}{2} \operatorname{tr}\left(X^{2}\right)} \mathrm{e}^{\Sigma_{j} t_{j} / j \operatorname{tr}\left(X^{j}\right)} \mathrm{d} \mu(X)  \tag{2.28}\\
&=\sum_{\substack{\Gamma \text { connected } \\
\text { ribbon graph }}} \frac{1}{\left|\operatorname{Aut}_{R}(\Gamma)\right|} n^{f(\Gamma)} \prod_{j} t_{j}^{v_{j}(\Gamma)} .
\end{align*}
$$

Indeed, the computation of $M(n, \mathbb{C})_{g, f}^{\text {or }}$ is just evaluating the trace of the identity matrix $I$. Each tadpole contributes

$$
\sum_{i, j} e_{i j} e_{i j}^{*}=\sum_{i, j} e_{i i}=n \cdot I
$$

while each bi-petal flower contributes

$$
\sum_{i, j, k, \ell} e_{i j} e_{k \ell} e_{j i} e_{\ell k}=\sum_{i, j} e_{i i} e_{j j}=I
$$

Therefore, we have

$$
M(n, \mathbb{C})_{g, f}^{\text {or }}=n^{2 g} n^{2(f-1)}\langle I\rangle=n^{-v+e+f} .
$$

Equation (2.28) follows from (2.27) and (2.26). Another useful form of hermitian matrix integral is

$$
\begin{align*}
& \log \int_{\mathcal{H}_{n, \mathrm{c}}} \mathrm{e}^{-\frac{1}{2} n \operatorname{tr}\left(X^{2}\right)} \mathrm{e}^{n \sum_{j} t_{j} / j \operatorname{tr}\left(X^{j}\right)} \mathrm{d} \mu(X)  \tag{2.28}\\
&=\sum_{\substack{\Gamma \text { connected } \\
\text { ribbon graph }}} \frac{1}{\left|\operatorname{Aut}_{R}(\Gamma)\right|} n^{\chi\left(S_{\Gamma}\right)} \prod_{j} t_{j}^{v_{j}(\Gamma)},
\end{align*}
$$

which also follows from (2.26).
Equation (2.28) is due to [6] and has been used by many authors in the study of hermitian matrix integrals [22], [35], [40], [41], [42], [43], [54]. In Section 4, we give another example of the general formula, where we consider $A=\mathbb{C}[G]$.

## 3. Integrals over a real von Neumann algebra.

For a finite-dimensional real von Neumann algebra $A$, the corresponding formulas become quite different. Since its trace is real valued, the hermitian inner product is real symmetric:

$$
\langle a, b\rangle=\left\langle a b^{*}\right\rangle=\left\langle b a^{*}\right\rangle=\langle b, a\rangle .
$$

The integral we wish to evaluate is

$$
\begin{equation*}
\sum_{\substack{\left(v_{1}, v_{2}, v_{3}, \ldots\right) \in \mathbb{N}^{\infty} \\ \mathrm{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)=n}} \int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{4}\left\langle x^{2}\right\rangle} \prod_{j \geq 1}^{\text {finite }} \frac{1}{v_{j}!\cdot(2 j)^{v_{j}}}\left\langle x^{j}\right\rangle^{v_{j}} \mathrm{~d} \mu(x) \tag{3.1}
\end{equation*}
$$

for every $n \geq 0$ with respect to a different normalized Lebesgue measure

$$
\begin{equation*}
\mathrm{d} \mu(x)=\frac{\mathrm{d} x}{\int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{4}\left\langle x^{2}\right\rangle} \mathrm{d} x} . \tag{3.2}
\end{equation*}
$$

The generating function for (3.1) is given by

$$
\begin{align*}
Z_{A}^{\mathbb{R}}(t) & =\int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{4}\left\langle x^{2}\right\rangle} \mathrm{e}^{\sum_{j=1}^{\infty} t_{j} / 2 j\left\langle x^{j}\right\rangle} \mathrm{d} \mu(x)  \tag{3.3}\\
& =\sum_{n=0}^{\infty} \sum_{\substack{\left(v_{1}, v_{2}, v_{3}, \ldots\right) \in \mathbb{N}^{\infty} \\
\mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)=n}} \prod_{j \geq 1}^{\infty} \frac{1}{v_{j}!\cdot(2 j)^{v_{j}}} \\
& \times \int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{4}\left\langle x^{2}\right\rangle} \prod_{j \geq 1}^{\text {finite }}\left\langle x^{j}\right\rangle^{v_{j}} \mathrm{~d} \mu(x) .
\end{align*}
$$

Lemma 3.1. - Let $A$ be a real von Neumann algebra. Then

$$
\begin{equation*}
\int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{4}\left\langle x^{2}\right\rangle} \prod_{j=1}^{n}\left\langle x^{j}\right\rangle^{v_{j}} \mathrm{~d} \mu(x)=\left.\prod_{j=1}^{n}\left\langle\left(\frac{\partial}{\partial y}\right)^{j}\right\rangle^{v_{j}} \mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}\right|_{y=0} . \tag{3.4}
\end{equation*}
$$

Proof. - The adjoint of the element $y \in A$ of Lemma 2.2 is given by

$$
y^{*}=\sum_{i-1}^{N} y_{i} e_{i}^{*}
$$

We note here that $y_{i} \in \mathbb{R}$ and the orthonormal basis $\left\{e_{1}, \ldots, e_{N}\right\}$ for $A$ is a real basis. Unlike the complex case, we have $\left\langle x y^{*}\right\rangle=\left\langle x^{*} y\right\rangle$, and hence

$$
\frac{\partial}{\partial y} \mathrm{e}^{\left\langle x y^{*}\right\rangle}=\frac{\partial}{\partial y} \mathrm{e}^{\left\langle x^{*} y\right\rangle}=x^{*} \mathrm{e}^{\left\langle x y^{*}\right\rangle}
$$

from Lemma 2.2. Therefore, for $x \in \mathcal{H}_{A}$,

$$
\frac{\partial}{\partial y} \mathrm{e}^{\left\langle\frac{1}{2} x\left(y+y^{*}\right)\right\rangle}=\frac{1}{2}\left(x+x^{*}\right) \mathrm{e}^{\left\langle\frac{1}{2} x\left(y+y^{*}\right)\right\rangle}=x \mathrm{e}^{\left\langle\frac{1}{2} x\left(y+y^{*}\right)\right\rangle}
$$

The completion of the square is modified to

$$
\begin{aligned}
\int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{4}\left\langle x^{2}\right\rangle} \mathrm{e}^{\left\langle\frac{1}{2} x\left(y+y^{*}\right)\right\rangle} \mathrm{d} \mu(x) & =\int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{4}\left\langle\left(x-\left(y+y^{*}\right)\right)^{2}\right\rangle} \mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle} \mathrm{d} \mu(x) \\
& =\mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}
\end{aligned}
$$

The rest of the proof is the same as the complex case.
To compute the RHS of (3.4), we first note

$$
\begin{aligned}
\frac{\partial}{\partial y} \mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle} & =\frac{1}{2} \sum_{i} \frac{\partial}{\partial y_{i}} e_{i}^{*} \mathrm{e}^{\frac{1}{4}\left\langle\left(\sum_{j} y_{j} e_{j}+\Sigma_{j} y_{j} e_{j}^{*}\right)^{2}\right\rangle} \\
& =\frac{1}{2} \sum_{i}\left\langle\left(y+y^{*}\right)\left(e_{i}+e_{i}^{*}\right)\right\rangle e_{i}^{*} \mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle} \\
& =\frac{1}{2} \sum_{i}\left\langle y+y^{*}, e_{i}+e_{i}^{*}\right\rangle e_{i}^{*} \mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle} \\
& =\left(y+y^{*}\right) \mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}
\end{aligned}
$$

In particular,

$$
\frac{\partial}{\partial y_{i}} \mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}=\frac{1}{2}\left\langle y+y^{*}, e_{i}+e_{i}^{*}\right\rangle \mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}
$$

and hence

$$
\begin{align*}
\left.\frac{\partial}{\partial y_{i}} \frac{\partial}{\partial y_{j}} \mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}\right|_{y=0} & =\left.\frac{1}{2} \frac{\partial}{\partial y_{i}}\left\langle y+y^{*}, e_{j}+e_{j}^{*}\right\rangle\right|_{y=0}  \tag{3.5}\\
& =\frac{1}{2}\left\langle e_{i}+e_{i}^{*}, e_{j}+e_{j}^{*}\right\rangle \\
& =\left\langle e_{i} e_{j}^{*}\right\rangle+\left\langle e_{i} e_{j}\right\rangle=\delta_{i j}+\left\langle e_{i} e_{j}\right\rangle .
\end{align*}
$$

This formula has an extra term $\delta_{i j}$ compared to (2.16). To compute the graphical expansion of

$$
\begin{equation*}
\left.\sum_{\substack{\left(v_{1}, v_{2}, v_{3}, \ldots\right) \in \mathbb{N}^{\infty} \\ \mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)=n}} \prod_{j \geq 1}^{\text {finite }} \frac{1}{v_{j}!\cdot(2 j)^{v_{j}}}\left\langle\left(\frac{\partial}{\partial y}\right)^{j}\right\rangle^{v_{j}} \mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}\right|_{y=0}, \tag{3.6}
\end{equation*}
$$

we proceed as before and assign a cyclically ordered $j$-valent vertex to each factor $\left\langle(\partial / \partial y)^{j}\right\rangle$ of the differentiation, assign the vertex contribution $\left\langle e_{i_{1}}^{*} \cdots e_{i_{j}}^{*}\right\rangle$ to it, and place the vertex consistently on an oriented plane with the clockwise orientation. When a pair of differentiation is applied, because of (3.5), there are now two choices: straight connection as in the ribbon graph case Figure 2.2 with a propagator $\left\langle e_{i} e_{j}\right\rangle$ assigned to the edge, or connection with a twisted edge carrying a propagator $\left\langle e_{i} e_{j}^{*}\right\rangle=\delta_{i j}$ as in Figure 3.1.

Figure 3.1. A half-edge labeled by $i_{3}$ of the left vertex is connected to a half-edge labeled by $j_{3}$ of the vertex at the right by a twisted edge. A propagator $\left\langle e_{i_{3}} e_{j_{3}}^{*}\right\rangle$ is assigned to this edge.

If the straight connection is used at every edge, then the resulting graph is a ribbon graph as before. Otherwise, we obtain a Möbius graph $\Gamma$ with some twisted edges. It has to be noted that the existence of twisted edges does not necessarily mean that the Möbius graph is non-orientable. For a Möbius graph $\Gamma$ thus obtained, let us define the graph contribution $A_{\Gamma}^{\mathbb{R}}$ as the sum with respect to all indices of the product of all vertex contributions $\left\langle e_{i_{1}}^{*} \cdots e_{i_{j}}^{*}\right\rangle$ and the product of all propagators, where $\left\langle e_{i} e_{j}\right\rangle$ is chosen for a straight edge and $\left\langle e_{i} e_{j}^{*}\right\rangle$ is chosen for a twisted edge.

The reality condition of the trace provides another invariance:

$$
\begin{equation*}
\left\langle e_{i_{1}}^{*} e_{i_{2}}^{*} \cdots e_{i_{j-1}}^{*} e_{i_{j}}^{*}\right\rangle=\left\langle e_{i_{j}} e_{i_{j-1}} \cdots e_{i_{2}} e_{i_{1}}\right\rangle \tag{3.7}
\end{equation*}
$$

This equality brings an equivalence relation into the set of Möbius graphs. To identify it, let us observe the following:

Lemma 3.2. - Let us denote by $\left\langle e_{i} e_{j}^{ \pm *}\right\rangle$ either $\left\langle e_{i} e_{j}\right\rangle$ or $\left\langle e_{i} e_{j}^{*}\right\rangle$, and use $\left\langle e_{i} e_{j}^{\mp *}\right\rangle$ to indicate the other propagator. Then

$$
\begin{align*}
\sum_{i_{1}, \ldots, i_{j}}\left\langle e_{i_{1}}^{*} \cdots e_{i_{j}}^{*}\right\rangle\left\langle e_{i_{1}} e_{h_{1}}^{ \pm *}\right\rangle & \cdots\left\langle e_{i_{j}} e_{h_{j}}^{ \pm *}\right\rangle  \tag{3.8}\\
& =\sum_{i_{1}, \ldots, i_{j}}\left\langle e_{i_{j}}^{*} \cdots e_{i_{1}}^{*}\right\rangle\left\langle e_{i_{1}} e_{h_{1}}^{\mp *}\right\rangle \cdots\left\langle e_{i_{j}} e_{h_{j}}^{\mp *}\right\rangle
\end{align*}
$$

Proof. - Using the contraction formula (2.11), the LHS is equal to $\left\langle e_{h_{1}}^{ \pm *} \cdots e_{h_{j}}^{ \pm *}\right\rangle$. Similarly, the RHS is equal to $\left\langle e_{h_{j}}^{\mp *} \cdots e_{h_{1}}^{\mp *}\right\rangle$. Because of the reality condition (3.7), these are actually the same.

Notice that the equation (3.8) is exactly the vertex flip operation of Figure 1.4. This allows us to define the graph contribution $A_{\Gamma}^{\mathbb{R}}$ slightly differently: it is the sum with respect to all indices of the product of all vertex contributions $\left\langle e_{i_{1}}^{*} \cdots e_{i_{j}}^{*}\right\rangle$ each of which has a cyclic order that is determined according to the cyclic order of the vertex, and the product of all propagators of edges determined by their twist. The extra redundancy of the vertex flip is compensated with the factor $(2 j)^{v_{j}}$ in front of (3.6), which is the order of the product of dihedral groups acting on the vertices through rotations and flips. In a parallel way with Proposition 2.4, we have thus established:

Proposition 3.3. - Let $M G(e)$ be the set of all Möbius graphs consisting of e edges. For each $j$-valent vertex of $\Gamma$, let us assign $\left\langle e_{i_{1}}^{*} \cdots e_{i_{j}}^{*}\right\rangle$, where the cyclic order of the product is determined by the cyclic order of the vertex. For every edge we assign a propagator $\left\langle e_{i_{k}} e_{h_{\ell}}\right\rangle$ if the edge is straight and $\left\langle e_{i_{k}} e_{h_{\ell}}^{*}\right\rangle$ if it is twisted. The incidence relation should be consistent with the labeling of half-edges, namely, the edge labeled with $i_{k} h_{\ell}$ connects the half-edge labeled by $i_{k}$ of a vertex to the half-edge labeled by $h_{\ell}$ from another vertex. Let $A_{\Gamma}^{\mathbb{R}}$ denote the sum with respect to all indices of the product of all contributions from vertices and edges. Then

$$
\begin{align*}
& \sum_{\begin{array}{c}
\left(v_{1}, v_{2}, v_{3}, \ldots\right) \in \mathbb{N}^{\infty} \\
\mathrm{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)=2 e
\end{array}} \int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{4}\left\langle x^{2}\right\rangle} \prod_{j \geq 1}^{\text {finite }} \frac{\left\langle x^{j}\right\rangle^{v_{j}}}{v_{j}!\cdot(2 j)^{v_{j}}} \mathrm{~d} \mu(x)  \tag{3.9}\\
&=\left.\sum_{\substack{\left(v_{1}, v_{2}, v_{3}, \ldots\right) \in \mathbb{N}^{\infty} \\
\mathbf{e}\left(v_{1}, v_{2}, v_{3}, \ldots\right)=2 e}} \prod_{j \geq 1}^{\text {finite }} \frac{1}{v_{j}!\cdot(2 j)^{v_{j}}}\left\langle\left(\frac{\partial}{\partial y}\right)^{j}\right\rangle^{v_{j}} \mathrm{e}^{\frac{1}{4}\left\langle\left(y+y^{*}\right)^{2}\right\rangle}\right|_{y=0} \\
&=\sum_{\Gamma \in M G(e)} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} A_{\Gamma}^{\mathbb{R}},
\end{align*}
$$

where $\operatorname{Aut}_{M}(\Gamma)$ is the automorphism group of $\Gamma$ as a Möbius graph.
If $\Gamma$ is orientable, then a series of vertex flip operations makes $\Gamma$ a ribbon graph, and for such a graph, $A_{\Gamma}^{\mathbb{R}}=A_{\Gamma}^{\text {or }}$. Although the von Neumann algebra $A$ is real, we can use the same definition of $A_{\Gamma}^{\text {or }}$ as in Proposition 2.4 for a real $A$. Its invariance with respect to the topological type of the orientable surface $S_{\Gamma}$ is the same as before. Even a Möbius graph $\Gamma$ is non-orientable, we still have the following:

Lemma 3.4. - Let $\Gamma$ be a connected Möbius graph with two or more vertices, and $E$ an edge of $\Gamma$ incident to two distinct vertices. Then the contribution of the graph $A_{\Gamma}^{\mathbb{R}}$ is invariant under the edge-contraction:

$$
\begin{equation*}
A_{\Gamma}^{\mathbb{R}}=A_{\Gamma / E}^{\mathbb{R}} \tag{3.10}
\end{equation*}
$$

Proof. - Let $V_{1}$ and $V_{2}$ be the two vertices incident to the edge $E$. If $E$ is not twisted, then the same argument of Lemma 2.5 applies. If the edge is twisted, then first apply a vertex flip operation to $V_{2}$ and untwist $E$. Then the situation is the same as before, and we can contract the edge, joining $V_{1}$ and $V_{2}$ together. We give the cyclic oder of $V_{1}$ as the new cyclic order to the newly created vertex.

It is known [23] that the set of all connected Möbius graphs with $f$ faces drawn on a closed non-orientable surface of cross-cap genus $k$ is connected with respect to the edge contraction and edge expansion moves. (These moves are called diagonal flips in [23].) Therefore, we can compute the invariant $A_{\Gamma}^{\mathbb{R}}$ for a non-orientable Möbius graph again by choosing our favorite graph. If we use a graph of Figure 3.2, then for every non-orientable Möbius graph of topological type $(k, f)$, the graph contribution is equal to

$$
\begin{equation*}
A_{k, f}^{\text {nor }}=\sum_{\substack{i_{1}, \ldots, i_{k} \\ h_{1}, \ldots, h_{f-1}}}\left\langle\left(e_{i_{1}}^{*}\right)^{2} \cdots\left(e_{i_{k}}^{*}\right)^{2} \cdot e_{h_{1}} e_{h_{1}}^{*} \cdots e_{h_{f-1}} e_{h_{f-1}}^{*}\right\rangle . \tag{3.11}
\end{equation*}
$$

Figure 3.2. A standard graph for a non-orientable surface of topological type $(k, f)$. It has $f-1$ tadpoles on the left, and $k$ twisted tadpoles on the right.

Now we have

Theorem 3.5. - The graphical expansion of the logarithm of the generating function $Z_{A}^{\mathbb{R}}(t)$ of (3.3) associated with a real von Neumann algebra $A$ is given by

$$
\begin{align*}
\log Z_{A}^{\mathbb{R}}(t)= & \log \int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{4}\left\langle x^{2}\right\rangle} \mathrm{e}^{\Sigma_{j} t_{j} / 2 j\left\langle x^{j}\right\rangle} \mathrm{d} \mu(x)  \tag{3.12}\\
= & \sum_{\begin{array}{c}
\Gamma \text { connected orientable } \\
\text { Möbius graph }
\end{array}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} A_{g(\Gamma), f(\Gamma)}^{\mathrm{or}} \prod t_{j}^{v_{j}(\Gamma)} \\
& \quad+\sum_{\substack{\Gamma \text { connected non- } \\
\text { orientable Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} A_{k(\Gamma), f(\Gamma)}^{\text {nor }} \prod_{j} t_{j}^{v_{j}(\Gamma)} .
\end{align*}
$$

For future convenience, we also record

$$
\begin{align*}
& \log \int_{\mathcal{H}_{A}} \mathrm{e}^{-\frac{1}{4} \alpha\left\langle x^{2}\right\rangle} \mathrm{e}^{\beta \sum_{j} t_{j} / 2 j\left\langle x^{j}\right\rangle} \mathrm{d} \mu(x)  \tag{3.13}\\
& \quad=\sum_{\substack{\Gamma \text { connected orientable } \\
\text { Möbius graph }}} \frac{\alpha^{-e(\Gamma)} \beta^{v(\Gamma)}}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} A_{g(\Gamma), f(\Gamma)}^{\mathrm{or}} \prod_{j} t_{j}^{v_{j}(\Gamma)} \\
& \quad+\sum_{\substack{\Gamma \text { connected non- } \\
\text { orientable Möbius graph }}} \frac{\alpha^{-e(\Gamma)} \beta^{v(\Gamma)}}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} A_{k(\Gamma), f(\Gamma)}^{\text {nor }} \prod_{j} t_{j}^{v_{j}(\Gamma)}
\end{align*}
$$

for a positive $\alpha$ and any $\beta$.
As an example of these formulas, let us consider the case when $A$ is a simple algebra. This time, it is isomorphic to either $M(n, \mathbb{R})$ or $M(n, \mathbb{H})$.

Example 3.1. - Let $A=M(n, \mathbb{R})$. Then as in Example 2.1, we can use $\left\{\sqrt{n} e_{i j}\right\}$ as our orthonormal basis. The space $\mathcal{H}_{A}$ of self-adjoint elements is the set of all real symmetric matrices $\mathcal{H}_{n, \mathbb{R}}$. Since elementary matrices are defined over the reals, we immediately see

$$
A_{g, f}^{\mathrm{or}}=n^{-v+e+f}
$$

as before. To calculate $A_{k, f}^{\text {nor }}$, we note that

$$
\left(e_{i_{1} j_{1}}\right)^{2} \cdots\left(e_{i_{k} j_{k}}\right)^{2}=0
$$

unless all $2 k$ indices are the same, and if they are the same, then the result is $e_{i i}$. Thus the sum of all these products is the identity matrix $I$. The contribution from the tadpoles of Figure 3.2 is the same as in Example 2.1, so we have

$$
\begin{align*}
& \log \int_{\mathcal{H}_{n, \mathbb{R}}} \mathrm{e}^{-\frac{1}{4} \operatorname{tr}\left(X^{2}\right)} \mathrm{e}^{\sum_{j} \frac{t_{j}}{2 j} \operatorname{tr}\left(X^{j}\right)} \mathrm{d} \mu(X)  \tag{3.14}\\
&=\sum_{\substack{\Gamma \text { connected } \\
\text { Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} n^{f(\Gamma)} \prod_{j} t_{j}^{v_{j}(\Gamma)},
\end{align*}
$$

or more conveniently,

$$
\begin{align*}
& \log \int_{\mathcal{H}_{n, \mathbb{R}}} \mathrm{e}^{-\frac{n}{4} \operatorname{tr}\left(X^{2}\right)} \mathrm{e}^{n \sum_{j} \frac{t_{j}}{2 j} \operatorname{tr}\left(X^{j}\right)} \mathrm{d} \mu(X)  \tag{3.15}\\
&=\sum_{\substack{\Gamma \text { connected } \\
\text { Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} n^{\chi\left(S_{\Gamma}\right)} \prod_{j} t_{j}^{v_{j}(\Gamma)} .
\end{align*}
$$

These formulas are well known (see for example, [9], [17]).
Example 3.2. - This time let us choose $A=M(n, \mathbb{H})$. As a real basis for quaternions, we use

$$
\mathrm{e}^{0}=\left(\begin{array}{ll}
1 &  \tag{3.16}\\
& 1
\end{array}\right), \quad \mathrm{e}^{1}=\left(\begin{array}{cc}
1 \\
-1 & 1
\end{array}\right), \quad \mathrm{e}^{2}=\left(\begin{array}{cc}
i & \\
& -i
\end{array}\right), \quad \mathrm{e}^{3}=\binom{-i}{-i} .
$$

The adjoint operation $\left(\mathrm{e}^{\mu}\right)^{*}$ on these $2 \times 2$ matrices is the same as the conjugate transposition $\left(\mathrm{e}^{\mu}\right)^{\dagger}$. A real basis for $M(n, \mathbb{H})$ is given by

$$
e_{i j}^{\nu}=e_{i j} \otimes \mathrm{e}^{\nu}, \quad i, j=1, \ldots, n, \quad \nu=0, \ldots, 3
$$

The normalized trace is defined by

$$
\left\langle e_{i j}^{\nu}\right\rangle=\frac{1}{2 n} \operatorname{tr}_{n \times n}\left(e_{i j}\right) \cdot \operatorname{tr}_{2 \times 2}\left(\mathrm{e}^{\nu}\right)
$$

for the basis elements and $\mathbb{R}$-linearly extended to all matrices. We notice that $\rangle$ is real valued because the $2 \times 2$ trace has value 0 for imaginary quaternionic units. With respect to the normalized trace, $\left\{\sqrt{n} e_{i j}^{\nu}\right\}$ is an orthonormal basis. The $*$-operation with respect the basis is given by

$$
\left(e_{i j}^{\nu}\right)^{*}=e_{j i} \otimes\left(\mathrm{e}^{\nu}\right)^{\dagger}
$$

The space of self-adjoint elements $\mathcal{H}_{A}=\mathcal{H}_{n, \mathbb{H}}$ consists of self-adjoint quatermionic matrices of size $n \times n$, and is spanned by $e_{i j} \otimes \mathrm{e}^{\nu}+e_{j i} \otimes\left(\mathrm{e}^{\nu}\right)^{\dagger}$. Note that the diagonal entries of a self-adjoint matrix are spanned by $e^{\nu}+\left(e^{\nu}\right)^{\dagger}$, and hence are real. Thus we have a real linear map

$$
\operatorname{tr}_{n \times n}: \mathcal{H}_{n, \mathbb{H}} \longrightarrow \mathbb{R}
$$

Since $e^{\nu}\left(e^{\nu}\right)^{\dagger}=e^{0}$, we have

$$
\sum_{i, j, \nu} e_{i j}^{\nu}\left(e_{i j}^{\nu}\right)^{*}=4 n I \otimes \mathrm{e}^{0}
$$

Similarly, $e^{0}=\left(e^{0}\right)^{2}=-\left(e^{1}\right)^{2}=-\left(e^{2}\right)^{2}=-\left(e^{3}\right)^{2}$, hence

$$
\sum_{i, j, \nu}\left(e_{i j}^{\nu}\right)^{2}=-2 I \otimes e^{0} .
$$

To compute $e_{i j}^{\mu} e_{k \ell}^{\nu}\left(e_{i j}^{\mu}\right)^{*}\left(e_{k \ell}^{\nu}\right)^{*}$, we use

$$
e^{\mu} e^{\nu}\left(e^{\mu}\right)^{\dagger}\left(e^{\nu}\right)^{\dagger}= \begin{cases}-e^{0} & \text { if } \mu, \nu>0, \mu \neq \nu  \tag{3.17}\\ +e^{0} & \text { otherwise }\end{cases}
$$

Therefore, of the 16 combinations, six cases are equal to $-e^{0}$ and ten are equal to $e^{0}$. Thus

$$
\sum_{\mu, \nu} e^{\mu} e^{\nu}\left(e^{\mu}\right)^{\dagger}\left(e^{\nu}\right)^{\dagger}=4 e^{0}
$$

and altogether, we have

$$
\sum_{i, j, k, \ell, \mu, \nu} e_{i j}^{\mu} e_{k \ell}^{\nu}\left(e_{i j}^{\mu}\right)^{*}\left(e_{k \ell}^{\nu}\right)^{*}=4 I \otimes e^{0}
$$

From all the above, we calculate

$$
\begin{aligned}
& M(n, \mathbb{H})_{g, f}^{\mathrm{or}}=\left(4 n^{2}\right)^{g}\left(4 n^{2}\right)^{f-1}\left\langle I \otimes \mathrm{e}^{0}\right\rangle=(2 n)^{-v+e+f} \\
& M(n, \mathbb{H})_{k, f}^{\mathrm{nor}}=(-2 n)^{k}\left(4 n^{2}\right)^{f-1}\left\langle I \otimes \mathrm{e}^{0}\right\rangle=(-1)^{k}(2 n)^{-v+e+f}
\end{aligned}
$$

Note that $(-1)^{k}=(-1)^{\chi\left(S_{\Gamma}\right)}$. Combining these computations with (3.13) and using the $n \times n$ trace of $M(n, \mathbb{H})$, we finally obtain

$$
\begin{align*}
& \log \int_{\mathcal{H}_{n, \text { HI }}} \mathrm{e}^{-\frac{1}{2} \operatorname{tr}\left(X^{2}\right)} \mathrm{e}^{\Sigma_{j} t_{j} / j \operatorname{tr}\left(X^{j}\right)} \mathrm{d} \mu(X)  \tag{3.18}\\
&=\sum_{\substack{\Gamma \text { connected } \\
\text { Möbius graph }}} \frac{(-1)^{\chi\left(S_{\Gamma}\right)}}{\left|\operatorname{Aut}_{M}(\Gamma)\right|}(2 n)^{f(\Gamma)} \prod_{j} t_{j}^{v_{j}(\Gamma)},
\end{align*}
$$

or equivalently,

$$
\begin{align*}
& \log \int_{\mathcal{H}_{n, \text { H }}} \mathrm{e}^{-n \operatorname{tr}\left(X^{2}\right)} \mathrm{e}^{2 n \sum_{j} t_{j} / j \operatorname{tr}\left(X^{j}\right)} \mathrm{d} \mu(X)  \tag{3.19}\\
&=\sum_{\substack{\Gamma \text { connected } \\
\text { Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|}(-2 n)^{\chi\left(S_{\Gamma}\right)} \prod_{j} t_{j}^{v_{j}(\Gamma)} .
\end{align*}
$$

These results are in agreement with recently established formulas found in [38].

## 4. Generating functions for the number of representations of surface groups.

Let us now turn our attention to the case of the complex group algebra $A=\mathbb{C}[G]$ of a finite group $G$. The $*$-operation is defined by

$$
\begin{equation*}
*: \mathbb{C}[G] \ni x=\sum_{w \in G} x(w) \cdot w \longmapsto x^{*}=\sum_{w \in G} \overline{x(w)} \cdot w^{-1} \in \mathbb{C}[G] . \tag{4.1}
\end{equation*}
$$

As the trace, we use

$$
\begin{equation*}
\left\rangle=\frac{1}{|G|} \chi_{\mathrm{reg}},\right. \tag{4.2}
\end{equation*}
$$

where $\chi_{\text {reg }}$ is the character of the regular representation of $G$ on $\mathbb{C}[G]$, linearly extended to the whole group algebra. The self-adjoint condition $x^{*}=x$ means $x\left(w^{-1}\right)=\overline{x(w)}$, and we have $\mathcal{H}_{\mathbb{C}[G]}=\mathbb{R}^{|G|}$ as a real vector space. A natural orthonormal basis for $\mathbb{C}[G]$ is the group $G$ itself, since we have

$$
\left\langle u v^{*}\right\rangle=\frac{1}{|G|} \chi_{\mathrm{reg}}\left(u v^{-1}\right)= \begin{cases}1 & \text { if } u=v \\ 0 & \text { otherwise. }\end{cases}
$$

It is because the normalized trace on $G$ takes value 1 only when the group element is the identity and 0 otherwise. Recall that

$$
\pi_{1}(S)=\left\langle a_{1}, b_{1}, \ldots, a_{g}, b_{g} \mid a_{1} b_{1} a_{1}^{-1} b_{1}^{-1} \cdots a_{g} b_{g} a_{g}^{-1} b_{g}^{-1}=1\right\rangle,
$$

where $S$ is an orientable surface of genus $g$. With respect the orthonormal basis, we immediately see

$$
\begin{align*}
\mathbb{C}[G]_{g, f}^{\text {or }} & =\sum_{u_{i}, v_{i}, w_{j} \in G}\left\langle u_{1} v_{1} u_{1}^{-1} v_{1}^{-1} \cdots u_{g} v_{g} u_{g}^{-1} v_{g}^{-1} \cdot w_{1} w_{1}^{-1} \cdots w_{f-1} w_{f-1}^{-1}\right\rangle  \tag{4.3}\\
& =|G|^{f-1} \cdot\left|\operatorname{Hom}\left(\pi_{1}(S), G\right)\right| .
\end{align*}
$$

Summarizing these facts and changing the constant factors using (2.26), we obtain a generating function of the number of homomorphisms from the fundamental group of an orientable surface into the finite group.

Theorem 4.1. - Let $G$ be a finite group. The following integral over the self-adjoint elements of the complex group algebra $\mathbb{C}[G]$ gives the
generating function for the cardinality of the representation variety of an orientable surface group in $G$ :
(4.4) $\log \int_{\mathcal{H}_{\mathbb{C}[G]}} \exp \left(-\frac{1}{2} \chi_{\mathrm{reg}}\left(x^{2}\right)\right) \exp \left(\sum_{j} \frac{t_{j}}{j} \chi_{\mathrm{reg}}\left(x^{j}\right)\right) \mathrm{d} \mu(x)$

$$
=\sum_{\substack{\Gamma \text { connected } \\ \text { ribbon graph }}} \frac{1}{\left|\operatorname{Aut}_{R} \Gamma\right|}|G|^{\chi\left(S_{\Gamma}\right)-1} \cdot\left|\operatorname{Hom}\left(\pi_{1}\left(S_{\Gamma}\right), G\right)\right| \cdot \prod_{j} t_{j}^{v_{j}(\Gamma)}
$$

Note that we have a von Neumann algebra isomorphism

$$
\begin{equation*}
\mathbb{C}[G] \cong \bigoplus_{\lambda \in \widehat{G}} \operatorname{End}\left(V_{\lambda}\right) \tag{4.5}
\end{equation*}
$$

which decomposes the character of the regular representation into the sum of irreducible characters:

$$
\chi_{\mathrm{reg}}=\sum_{\lambda \in \widehat{G}}(\operatorname{dim} \lambda) \chi_{\lambda}=\sum_{\lambda \in \widehat{G}}(\operatorname{dim} \lambda) \operatorname{tr}_{\lambda},
$$

where $\operatorname{dim} \lambda$ is the dimension of $\lambda \in \widehat{G}$ and $\chi_{\lambda}$ is its character. Therefore, using (2.29) for each irreducible factor, we calculate

$$
\begin{aligned}
& \text { (4.6) } \log \int_{\mathcal{H}_{\mathbb{C}[G]}} \exp \left(-\frac{1}{2} \chi_{\mathrm{reg}}\left(x^{2}\right)\right) \exp \left(\sum_{j} \frac{t_{j}}{j} \chi_{\mathrm{reg}}\left(x^{j}\right)\right) \mathrm{d} \mu(x) \\
& =\log \int_{\mathcal{H}_{\mathrm{C}[G]}} \prod_{\lambda \in \widehat{G}} \exp \left(-\frac{\operatorname{dim} \lambda}{2} \operatorname{tr}_{\lambda}\left(x^{2}\right)\right) \exp \left(\operatorname{dim} \lambda \sum_{j} \frac{t_{j}}{j} \operatorname{tr}_{\lambda}\left(x^{j}\right)\right) \mathrm{d} \mu_{\lambda}(x) \\
& =\sum_{\lambda \in \widehat{G}} \log \int_{\mathcal{H}_{\operatorname{dim} \lambda, \mathrm{C}}} \exp \left(-\frac{\operatorname{dim} \lambda}{2} \operatorname{tr}_{\lambda}\left(x^{2}\right)\right) \exp \left(\operatorname{dim} \lambda \sum_{j} \frac{t_{j}}{j} \operatorname{tr}_{\lambda}\left(x^{j}\right)\right) \mathrm{d} \mu_{\lambda}(x) \\
& =\sum_{\substack{\Gamma \text { connected } \\
\text { ribbon graph }}} \frac{1}{\left|\operatorname{Aut}_{R} \Gamma\right|} \sum_{\lambda \in \widehat{G}}(\operatorname{dim} \lambda)^{\chi\left(S_{\Gamma}\right)} \prod_{j} t_{j}^{v_{j}(\Gamma)},
\end{aligned}
$$

where $\mathrm{d} \mu_{\lambda}$ is the normalized Lebesgue measure on the space of $\operatorname{dim} \lambda \times \operatorname{dim} \lambda$ hermitian matrices. Comparing expressions (4.4) and (4.6), we recover Mednykh's formula (0.7):

$$
\sum_{\lambda \in \widehat{G}}(\operatorname{dim} \lambda)^{\chi(S)}=|G|^{\chi(S)-1} \cdot\left|\operatorname{Hom}\left(\pi_{1}(S), G\right)\right| .
$$

Remark. - Another proof of Mednykh's formula is found in [13], which uses Chern-Simons gauge theory with a finite gauge group. Burnside asked a related question on p. 319 (§ 238, Ex. 7) of his textbook [10]. The formula for genus 1 case is found in Frobenius [14] of 1896. We refer to [48] for the relation of these formulas to combinatorics. An excellent historical account on this and Frobenius-Schur formula (0.9) is found in [26].

Now consider the real group algebra $\mathbb{R}[G]$. For a non-orientable surface of cross-cap genus $k$, we know

$$
\pi_{1}(S)=\left\langle a_{1}, \ldots, a_{k} \mid a_{1}^{2} \cdots a_{k}^{2}=1\right\rangle
$$

Therefore,

$$
\begin{align*}
\mathbb{R}[G]_{k, f}^{\mathrm{nor}} & =\sum_{u_{i}, w_{j} \in G}\left\langle u_{1}^{2} \cdots u_{k}^{2} \cdot w_{1}^{-1} w_{1} \cdots w_{f-1}^{-1} w_{f-1}\right\rangle  \tag{4.7}\\
& =|G|^{f-1} \cdot\left|\operatorname{Hom}\left(\pi_{1}(S), G\right)\right| .
\end{align*}
$$

Our general formula (3.13) yields

Theorem 4.2. - Let $G$ be a finite group. The following integral over the space of self-adjoint elements of the real group algebra $\mathbb{R}[G]$ gives the generating function for the number of homomorphisms from the fundamental group of a closed surface into $G,\left|\operatorname{Hom}\left(\pi_{1}(S), G\right)\right|$, for all $S$, including orientble and non-orientable surfaces.

$$
\begin{aligned}
& \log \int_{\mathcal{H}_{\mathbb{R}[G]}} \mathrm{e}^{-\frac{1}{4} \chi_{\mathrm{reg}}\left(x^{2}\right)} \mathrm{e}^{\frac{1}{2} \sum_{j} t_{j} / j \chi_{\mathrm{reg}}\left(x^{j}\right)} \mathrm{d} \mu(x) \\
& =\sum_{\substack{\Gamma \text { connected } \\
\text { Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M} \Gamma\right|}|G|^{\chi\left(S_{\Gamma}\right)-1} \cdot\left|\operatorname{Hom}\left(\pi_{1}\left(S_{\Gamma}\right), G\right)\right| \prod_{j} t_{j}^{v_{j}(\Gamma)} .
\end{aligned}
$$

Recall that the real group algebra $\mathbb{R}[G]$ decomposes into simple factors according to the three types of irreducible representations (0.8). Notice that $\widehat{G}_{1}$ consists of complex irreducible representations of $G$ that are defined over $\mathbb{R}$. A representation in $\widehat{G}_{2}$ is not defined over $\mathbb{R}$, and its character is not real-valued. Thus the complex conjugation acts on the set $\widehat{G}_{2}$ without fixed points. Let $\widehat{G}_{2+}$ denote a half of $\widehat{G}_{2}$ such that

$$
\begin{equation*}
\widehat{G}_{2+} \cup \overline{\widehat{G}_{2+}}=\widehat{G}_{2} \tag{4.9}
\end{equation*}
$$

A complex irreducible representation of $G$ that belongs to $\widehat{G}_{4}$ admits a skew-symmetric bilinear form. In particular, its dimension (over $\mathbb{C}$ ) is even. Now we have a von Neumann algebra isomorphism

$$
\begin{equation*}
\mathbb{R}[G] \cong \bigoplus_{\lambda \in \widehat{G}_{1}} \operatorname{End}_{\mathbb{R}}\left(\lambda^{\mathbb{R}}\right) \oplus \bigoplus_{\lambda \in \widehat{G}_{2+}} \operatorname{End}_{\mathbb{C}}(\lambda) \oplus \bigoplus_{\lambda \in \widehat{G}_{4}} \operatorname{End}_{\mathbb{H}}\left(\lambda^{\mathbb{H}}\right) \tag{4.10}
\end{equation*}
$$

where $\lambda^{\mathbb{R}}$ is a real irreducible representation of $G$ that satisfies $\lambda=\lambda^{\mathbb{R}} \otimes_{\mathbb{R}} \mathbb{C}$. The representation space $\lambda^{\mathbb{H}}$ is a $\frac{1}{2} \operatorname{dim} \lambda$-dimensional vector space defined over $\mathbb{H}$ for $\lambda \in \widehat{G}_{4}$ such that its image under the natural injection

$$
\begin{equation*}
\operatorname{End}_{\mathbb{H}}\left(\lambda^{\mathbb{H}}\right) \longrightarrow \operatorname{End}_{\mathbb{C}}(\lambda) \tag{4.11}
\end{equation*}
$$

coincides with the image of

$$
\rho_{\lambda}: \mathbb{R}[G] \longrightarrow \operatorname{End}_{\mathbb{C}}(\lambda),
$$

where $\rho_{\lambda}$ is the representation of $\mathbb{R}[G]$ corresponding to $\lambda \in \widehat{G}$. The injective algebra homomorphism (4.11) is defined by the $2 \times 2$ matrix representation of the quaternions (3.16). The algebra isomorphism (4.10) gives a formula for the character of the regular representation on $\mathbb{R}[G]$ :

$$
\begin{align*}
\chi_{\mathrm{reg}} & =\sum_{\lambda \in \widehat{G}_{1}}(\operatorname{dim} \lambda) \chi_{\lambda}+\sum_{\lambda \in \widehat{G}_{2+}}(\operatorname{dim} \lambda)\left(\chi_{\lambda}+\overline{\chi \lambda}\right)  \tag{4.12}\\
& +\sum_{\lambda \in \widehat{G}_{4}} 2(\operatorname{dim} \lambda) \cdot \operatorname{trace}_{\lambda^{\mathbb{H}}}
\end{align*}
$$

where in the last term the character is given as the trace of quaternionic $\left(\frac{1}{2} \operatorname{dim} \lambda\right) \times\left(\frac{1}{2} \operatorname{dim} \lambda\right)$ matrices. Notice that if $\lambda \in \widehat{G}_{2}$, then for every $x=x^{*} \in \mathcal{H}_{\mathbb{R}[G]}$, we have

$$
\chi_{\lambda}(x)=\overline{\chi_{\lambda}}(x)=\operatorname{tr}_{\operatorname{dim} \lambda}\left(\rho_{\lambda}(x)\right)
$$

since $\rho_{\lambda}(x)$ is a hermitian matrix of size $\operatorname{dim} \lambda \times \operatorname{dim} \lambda$.
The integration (4.8) can be carried out using (2.29), (3.15) and (3.19) with the decomposition (4.10) and (4.12). The result is

$$
\begin{aligned}
& \log \int_{\mathcal{H}_{\mathbb{R}[G]}} \mathrm{e}^{-\frac{1}{4} \chi_{\mathrm{reg}}\left(x^{2}\right)} \mathrm{e}^{\frac{1}{2} \sum_{j} \frac{t_{j}}{j} \chi_{\mathrm{reg}}\left(x^{j}\right)} \mathrm{d} \mu(x) \\
& \quad=\sum_{\lambda \in \widehat{G}_{1}} \log \int_{\mathcal{H}_{\mathrm{dim}} \lambda, \mathbb{R}} \mathrm{e}^{-\frac{1}{4} \operatorname{dim} \lambda \operatorname{tr}\left(x^{2}\right)} \mathrm{e}^{\operatorname{dim} \lambda \sum_{j} \frac{t_{j}}{2 j} \operatorname{tr}\left(x^{j}\right)} \mathrm{d} \mu_{\lambda}(x)
\end{aligned}
$$

$$
\begin{aligned}
& +\sum_{\lambda \in \widehat{G}_{2}} \log \int_{\mathcal{H}_{\operatorname{dim} \lambda, \mathrm{C}}} \mathrm{e}^{-\frac{1}{4} \operatorname{dim} \lambda \operatorname{tr}\left(x^{2}\right)} \mathrm{e}^{\operatorname{dim} \lambda \sum_{j}{ }^{\frac{t_{j}}{2 j}} \operatorname{tr}\left(x^{j}\right)} \mathrm{d} \mu_{\lambda}(x) \\
& +\sum_{\lambda \in \widehat{G}_{4}} \log \int_{\mathcal{H}_{\frac{1}{2} \operatorname{dim} \lambda, \mathbb{H}}} \mathrm{e}^{-\frac{1}{2} \operatorname{dim} \lambda \operatorname{tr}\left(x^{2}\right)} \mathrm{e}^{\operatorname{dim} \lambda \sum_{j} \frac{t_{j}}{j} \operatorname{tr}_{\frac{1}{2} \operatorname{dim} \lambda}\left(x^{j}\right)} \mathrm{d} \mu_{\lambda}(x) \\
& =\sum_{\substack{\Gamma \text { connected } \\
\text { Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} \sum_{\lambda \in \widehat{G}_{1}}(\operatorname{dim} \lambda)^{\chi\left(S_{\Gamma}\right)} \prod_{j} t_{j}^{v_{j}(\Gamma)} \\
& +\sum_{\substack{\Gamma \text { connected orientable } \\
\text { Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} \sum_{\lambda \in \widehat{G}_{2}}(\operatorname{dim} \lambda)^{\chi\left(S_{\Gamma}\right)} \prod_{j} t_{j}^{v_{j}(\Gamma)} \\
& +\sum_{\substack{\Gamma \text { connected } \\
\text { Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} \sum_{\lambda \in \widehat{G}_{4}}(-\operatorname{dim} \lambda)^{\chi\left(S_{\Gamma}\right)} \prod_{j} t_{j}^{v_{j}(\Gamma)} \\
& =\sum_{\substack{\Gamma \text { connected orientable } \\
\text { Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} \sum_{\lambda \in \widehat{G}}(\operatorname{dim} \lambda)^{\chi\left(S_{\Gamma}\right)} \prod_{j} t_{j}^{v_{j}(\Gamma)} \\
& +\sum_{\substack{\Gamma \text { connected non- } \\
\text { orientable Möbius }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} \sum_{\lambda \in \widehat{G}_{1}}(\operatorname{dim} \lambda)^{\chi\left(S_{\Gamma}\right)} \prod_{j} t_{j}^{v_{j}(\Gamma)} \\
& \text { orientable Möbius graph } \\
& +\sum_{\substack{\Gamma \text { connected non- } \\
\text { orientable Möbius graph }}} \frac{1}{\left|\operatorname{Aut}_{M}(\Gamma)\right|} \sum_{\lambda \in \widehat{G}_{4}}(-\operatorname{dim} \lambda)^{\chi\left(S_{\Gamma}\right)} \prod_{j} t_{j}^{v_{j}(\Gamma)} .
\end{aligned}
$$

Notice that the sum over orientable Möbius graphs recovers Mednykh's formula (0.7) again, because the Euler characteristic $\chi(S)$ is even for an orientable surface. From the sum over non-orientable Möbius graphs, we obtain the formula of Frobenius-Schur (0.9) of [15]:

$$
\sum_{\lambda \in \widehat{G}_{1}}(\operatorname{dim} \lambda)^{\chi(S)}+\sum_{\lambda \in \widehat{G}_{4}}(-\operatorname{dim} \lambda)^{\chi(S)}=|G|^{\chi(S)-1} \cdot\left|\operatorname{Hom}\left(\pi_{1}(S), G\right)\right| .
$$

Note that the $\widehat{G}_{2}$ component has no contribution in this formula. This is due to the fact that graphical expansion of a complex hermitian matrix integral contains only orientable ribbon graphs.
